Summary

This **Electronic Supplementary Material (S1)** includes:

- more information about the *primary data* used in this paper and its coding (**Tables S1**, **S3**, **S4** and **S15**);
- the relationships between the language family *stability profiles* (**Tables S2** and **S5**, and **Figures S1-S14**);
- the *involvement* of different features in sets maximizing the correlations between geographic and stability distances (**Tables S6-S13**);
- the *combined p-values* (**Tables S14** and **S16**);
- the *punctuated evolution* of structural features (**Tables S18** and **S19**, and **Figures S15-S18**); and
- the *R code* implementing the five methods for combining *p*-values (**Table S17**).

The order of these items largely reflects the structure of the paper's main text.

Table of Contents

Supplementary Figures

Supplementary Tables

Dataset	Software	Coding	Classification	Structural features	Language families	Languages
MBE	MrBayes	Binary	Ethnologue	86	33	320

Table S2*: Comparison between the observed stability distances between the actual language families and 10,000 simulations of random language families.* ***Diag****: the maximum possible stability distance in the stability cube with the number of dimensions equal to the number of features in this case.* ***Measure****: the summary of the stability distances matrix between language families (**NN** is the average distance to the nearest neighbor; **Mean** is the mean stability distance).* ***Observed****: the actual value of the measure for the real language families.* ***Simulated****: 10,000 simulations of random language families in the current stability cube resulting in 10,000 simulated stability distance matrices; for each such simulated matrix the measures as defined above have been computed and the distribution of these 10,000 simulated measures was summarized using their **Mean** and standard deviation (**SD**); **SDs from mean** represents how far is the observed measure from the mean of the simulated measures in terms of the simulated SDs.* ***P-value****: the empirical probability that the observed measure is outside the simulated distribution.*

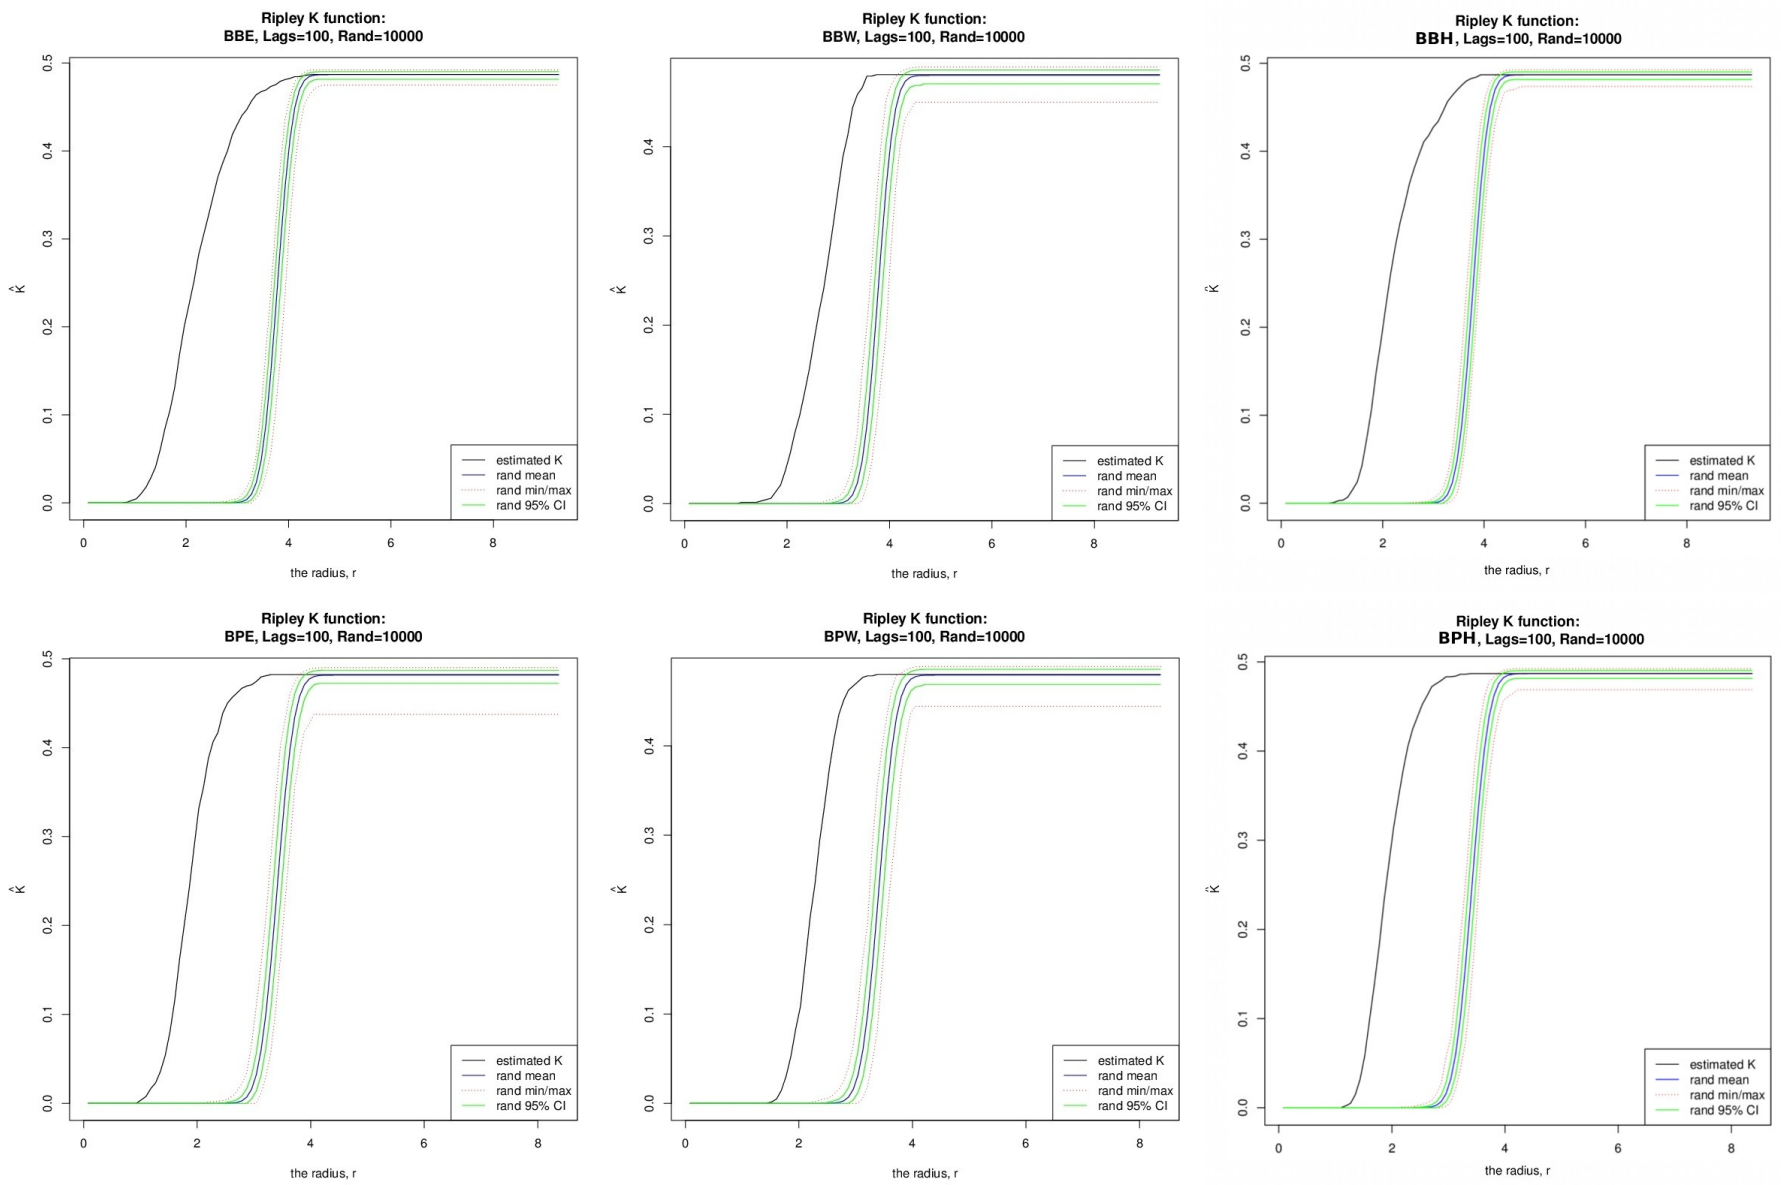

Figure S1*: The observed Ripley's* ***K*** *function (computed at 100 lags) for the 4 datasets using BayesLang versus 10,000 simulated Poisson processes. It can be seen that the actually observed values (black) are well outside the 95% confidence interval around the mean randomizations (and, in fact, outside their whole range) for all meaningful values of the radius r.*

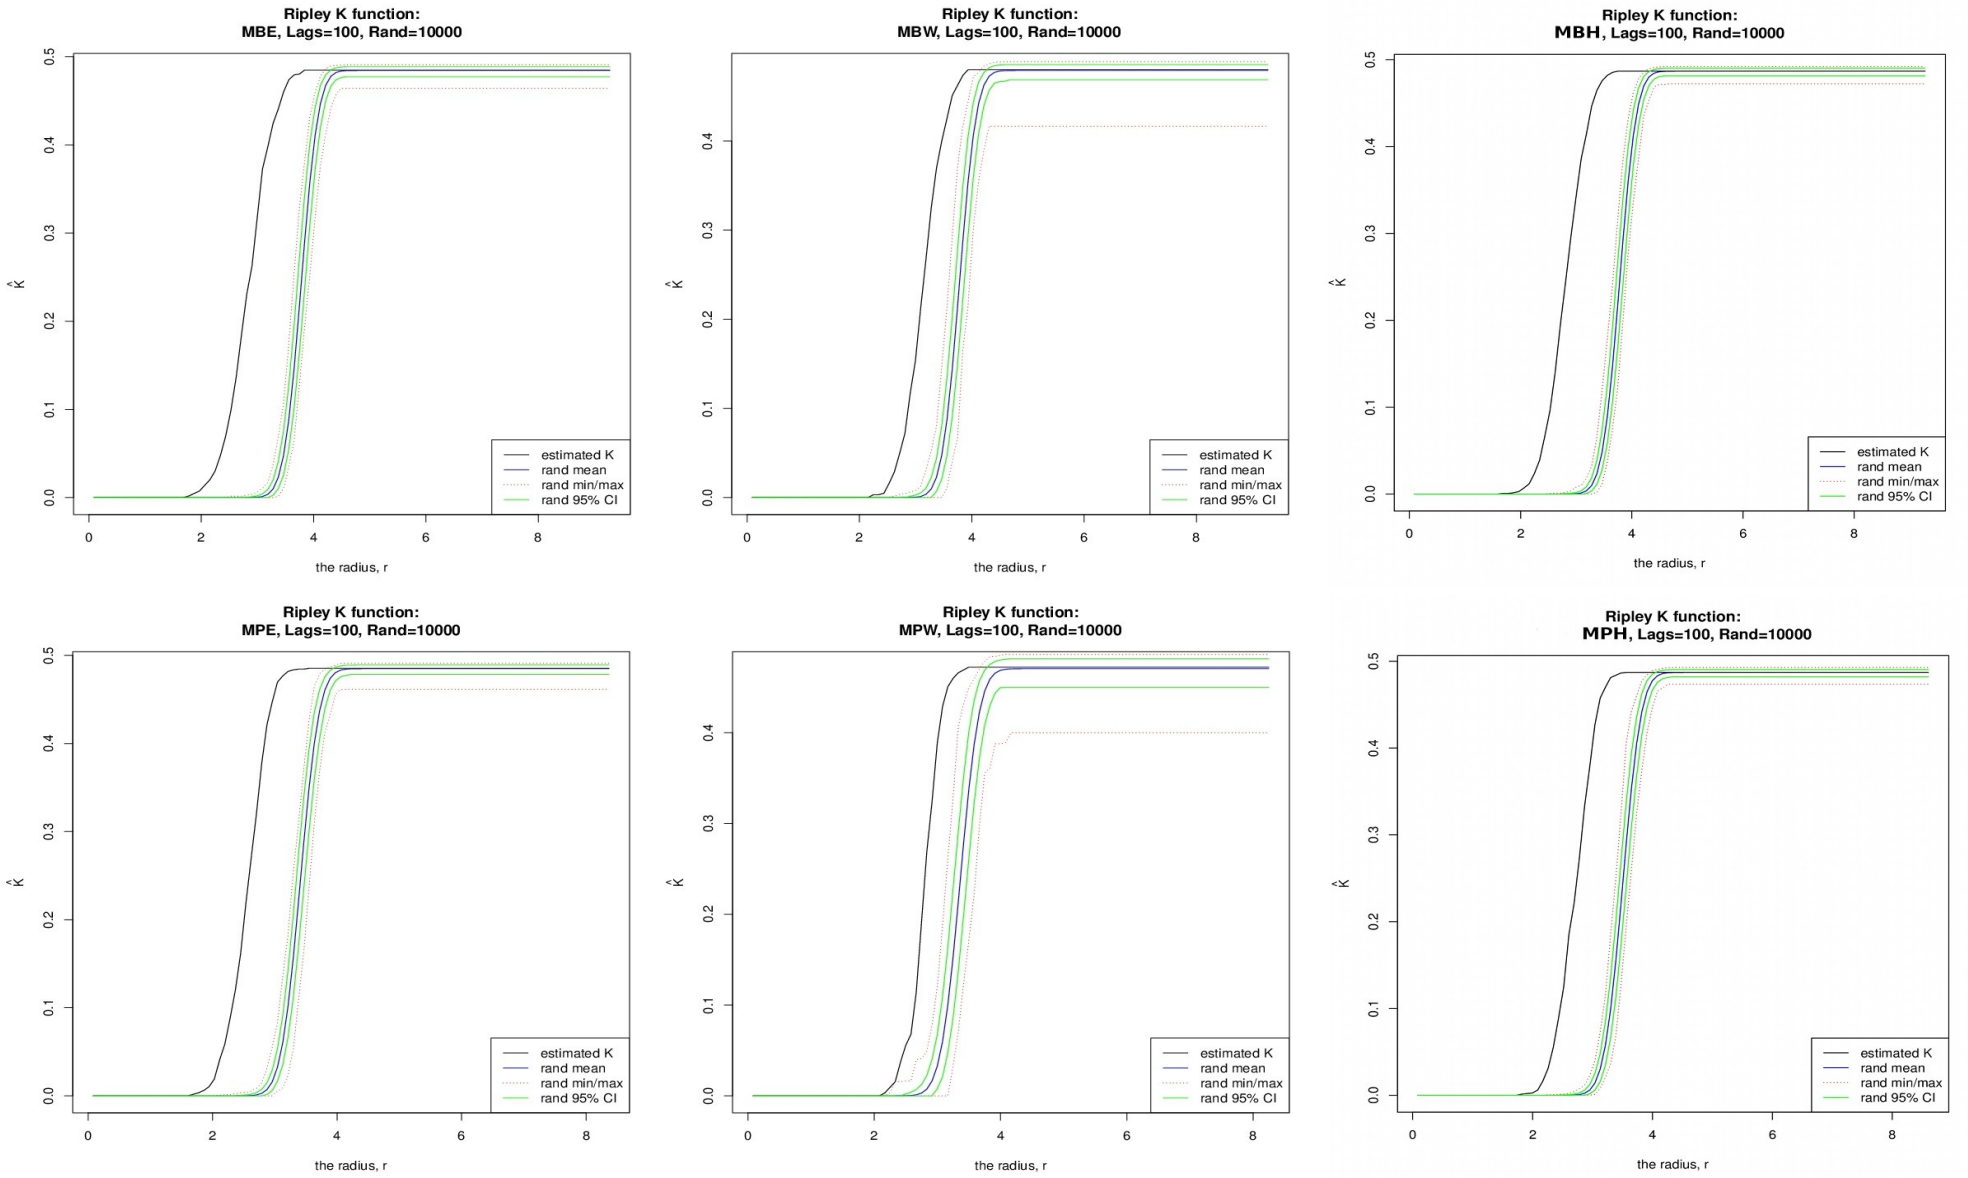

***Figure S2**: The observed Ripley's **K** function (computed at 100 lags) for the 4 datasets using MrBayes versus 10,000 simulated Poisson processes. It can be seen that the actually observed values (black) are well outside the 95% confidence interval around the mean randomizations (and, in fact, outside their whole range) for all meaningful values of the radius r.*

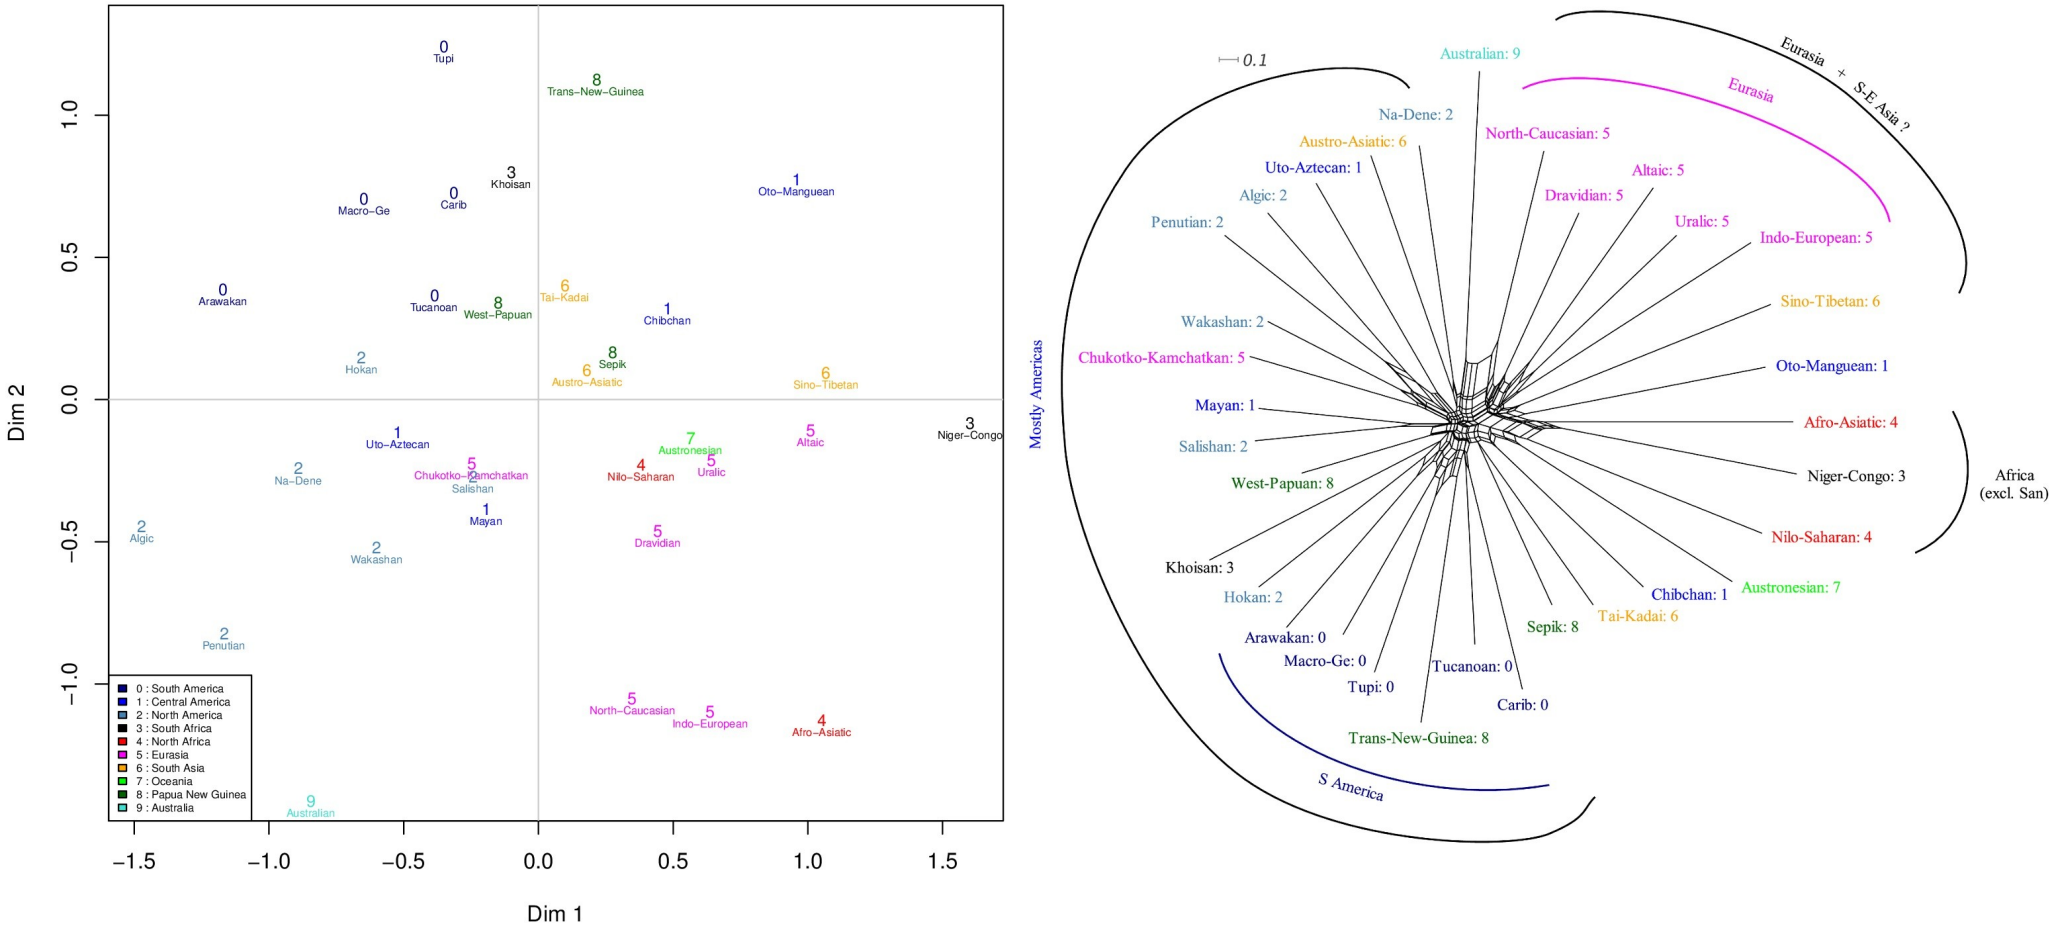

Figure S3: *MDS (left) and annotated Network (right) representations of the stability distances between language families for dataset* ***MBE****. Please note that for the MDS plot only the first two dimensions are shown and the scales and directionality of the axes are arbitrary.*

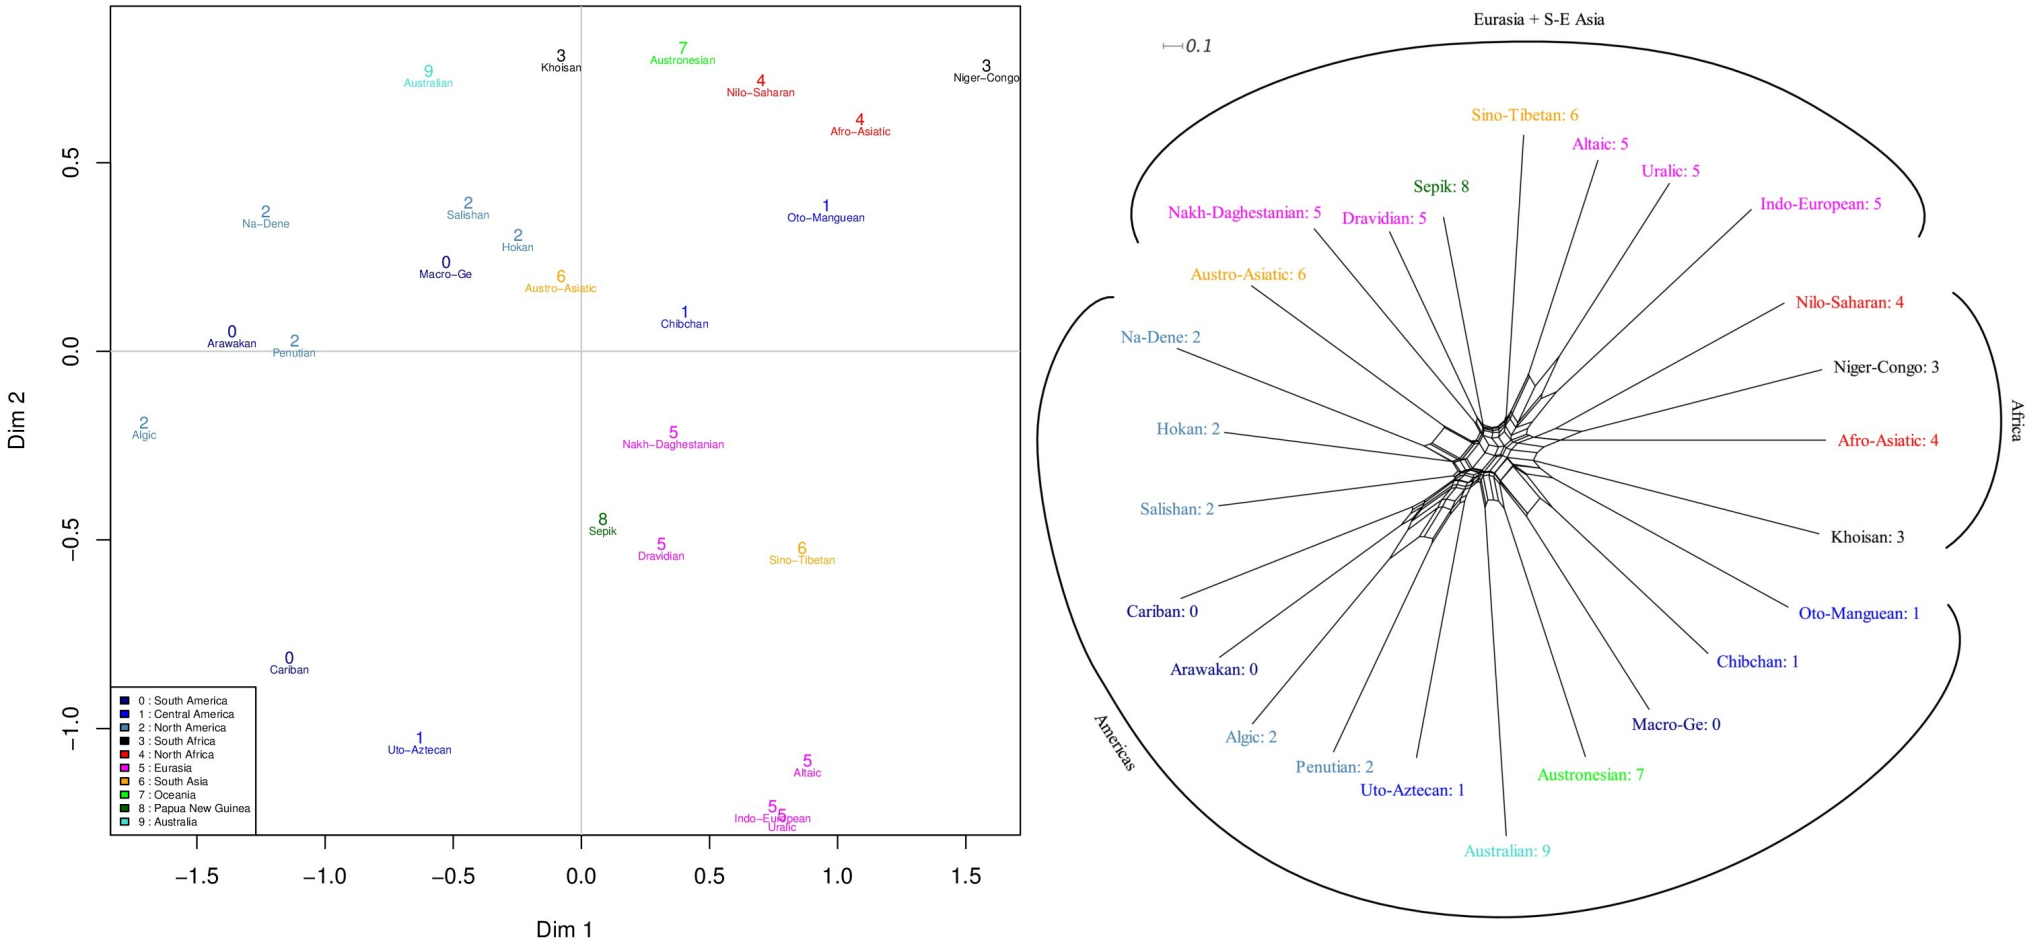

Figure S4: *MDS (left) and annotated Network (right) representations of the stability distances between language families for dataset* ***MBW***. *Please note that for the MDS plot only the first two dimensions are shown and the scales and directionality of the axes are arbitrary.*

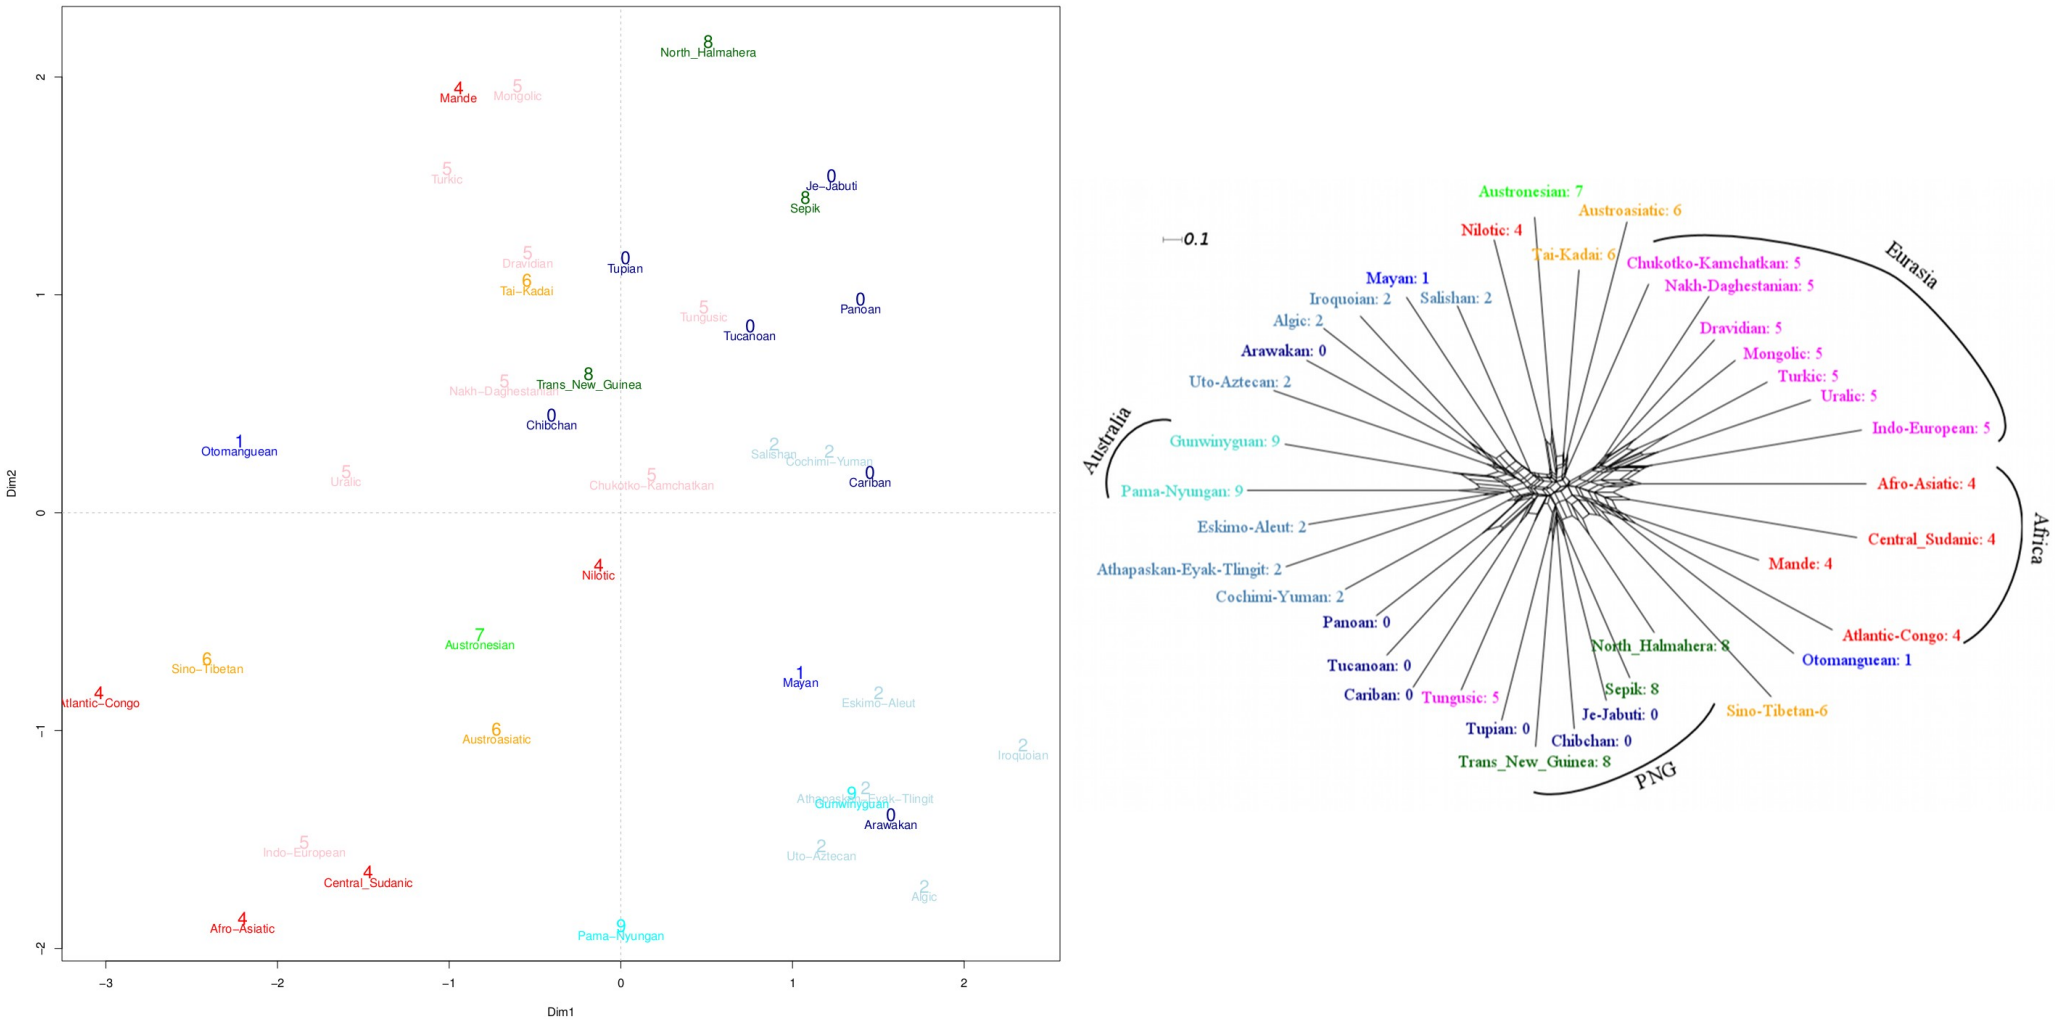

Figure S5*: MDS (left) and annotated Network (right) representations of the stability distances between language families for dataset* ***MBH****. Please note that for the MDS plot only the first two dimensions are shown and the scales and directionality of the axes are arbitrary.*

Table S4: *The composition and structure of the language families can vary among cases. The structure is given as the topology of the language family in the parentheses notation (Newick format; http://evolution.genetics.washington.edu/phylip/newicktree.html). The languages are given using their ISO 639-2 three-letter codes. The number of families and their composition might differ slightly among outgroups for MrBayes.*

Z-transform	Hartung	0.97	$< 2.2 \cdot 10^{-16}$	24	20	1	5	26.60	$2.50 \cdot 10^{-7}$
	Makambi	0.90	$< 2.2 \cdot 10^{-16}$	27	18	3	2	28.33	$1.02 \cdot 10^{-7}$
	Simes	-	-	20	18	3	9	12.54	0.0004
Hartung	Makambi	0.93	$< 2.2 \cdot 10^{-16}$	25	20	5	0	30.08	$4.14 \cdot 10^{-8}$
	Simes	-	-	21	23	2	4	26.09	$3.26 \cdot 10^{-7}$
Simes	Makambi	-	-	23	20	7	0	25.39	$4.68 \cdot 10^{-7}$

Table S14*: Correlations and concordances between methods for combining p-values. There is very high agreement between these methods on our data. The* ***correlation*** *represents the Pearson's correlation coefficient between the combined p-values provided by the methods (please note that Simes does not compute a combined p-value and only provides a decision to reject/not reject H_0 at the chosen α-level). If we take the α-level to be 0.05, then these tests reject or not the H_0 and the columns* ***T-T****,* ***F-F****,* ***T-F*** *and* ***F-F*** *represent the number of times the two tests both reject H_0, both fail to reject it, only the first does reject and only the second, respectively. The last two columns show the χ^2 test on this contingency table.*

Macro-area	Interpretation	Dataset	Composition
Africa[1]	Do all the African language families form a group?	**MBE**	*Afro-Asiatic, Khoisan, Niger-Congo, Nilo-Saharan*

1 Given that the **H** classification does not contain "*Khoisan*" or an equivalent grouping, for the four datasets using it (**MBH**, **MPH**, **BBH** and **BPH**) **Africa** and **Africa (w/o Khoisan)** are equivalent. We considered it equivalent to **Africa** as it conceptually tests the coherence of the whole continent with respect to the rest of the world.

Macro-area	Interpretation	Dataset	Composition
		BPH	*Algic, Arawakan, Athapaskan-Eyak-Tlingit, Cariban, Chibchan, Cochimi-Yuman, Eskimo-Aleut, Iroquoian, Je-Jabuti, Mayan, Otomanguean, Panoan, Salishan, Tucanoan, Tupian, Uto-Aztecan*

Table S15*:The sets of language families considered with their interpretation and composition for each dataset.*

2 Only classification **H** proposes more than a single language family for **Australia** (the other two have a single controversial construct "*Australian*"), making the testing of this hypothesis possible only for the four datasets using **H** (**MBH**, **MPH**, **BBH** and **BPH**).

† A combined *p*-value of exactly 0.00 is an artifact of combining very small randomization *p*-values (smaller than the lower limit given by the number of randomizations used here, 10^{-4}) and represents in fact an extremely small (but still greater than 0) *p*-value.

‡ For tests involving **Siberia** (N-E Eurasia), the **first** entry in the **H** cells represents *Chukotko-Kamchatkan* & *Tungusic* while the **second** entry represents *Chukotko-Kamchatkan* only; this extends to the combined *p*-value cells.

***Table S16**: Statistical robustness of sets of language families. Actual p-values for each of the datasets and the combined p-values using the five methods (**F**isher, **Z**-transform, **H**artung, **S**imes and **M**akambi) applied to all datasets for raw (**Geo** is "No") and geography-corrected (**Geo** is "Yes") stability distances. Also showing the paired t-tests between the raw and geography-corrected p-values (**bold**=significant t-test, italic=positive t-test). For **S** we show if H_0 was rejected ("Yes" or "No") for α=0.05. For **H** and **M** the estimated inter-datasets correlations are also shown. The most **conservative** combined p-value among the methods is in bold. Significant p-values at α=0.05 are in italic. See **Table S15** for the actual composition of the sets of families.*

***Table S18**: The correlations between branch length and number of nodes for all language families amalgamated (first line) and each family separately for each of the 8*

datasets containing the family. Both Pearson's r and Spearman's ρ are given and the vast majority is very highly significant due to the very large number of observations in the posterior distribution, except for those marked with † which are non-significant at an α-level of 0.05. We considered for this test only the datasets using the Ethnologue and Harald Hammarstöm's classifications given that they have an unconstrained number of levels.

Table S19*: The correlations between branch length and number of nodes for all types of categories separately for each of the 4 datasets considered. Reported are the mean and standard deviation of Pearson's r across language families and outgroups. We considered for this test only the datasets using Harald Hammarstöm's classification given the computational cost. N=1 considers all families, while N=5 and N=7 only those with data for at least 5 or for all 7 categories.*

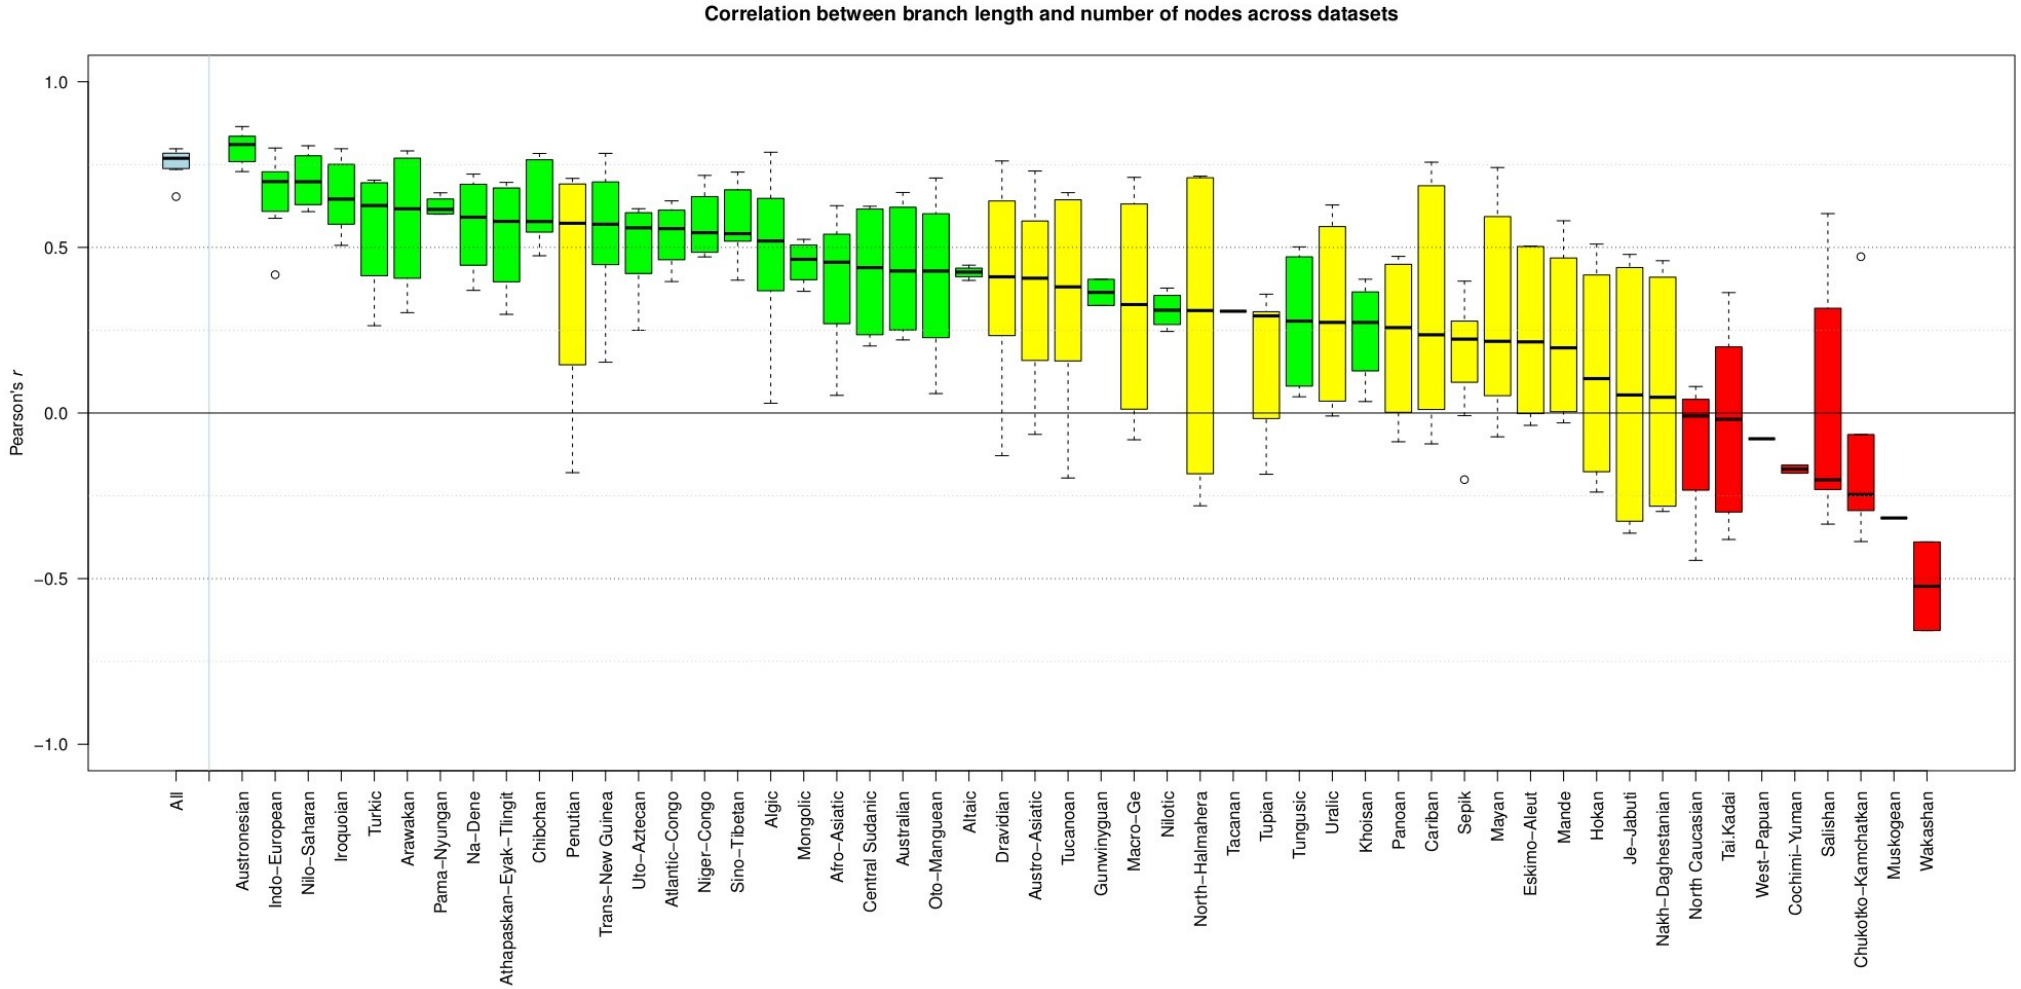

Figure S15*: Correlation between branch length and number of nodes for all families together (leftmost) and for each family individually. The boxplots summarize the Pearson's r across the 8 datasets, red means the median r is below 0, yellow that the minimum r is below 0.*

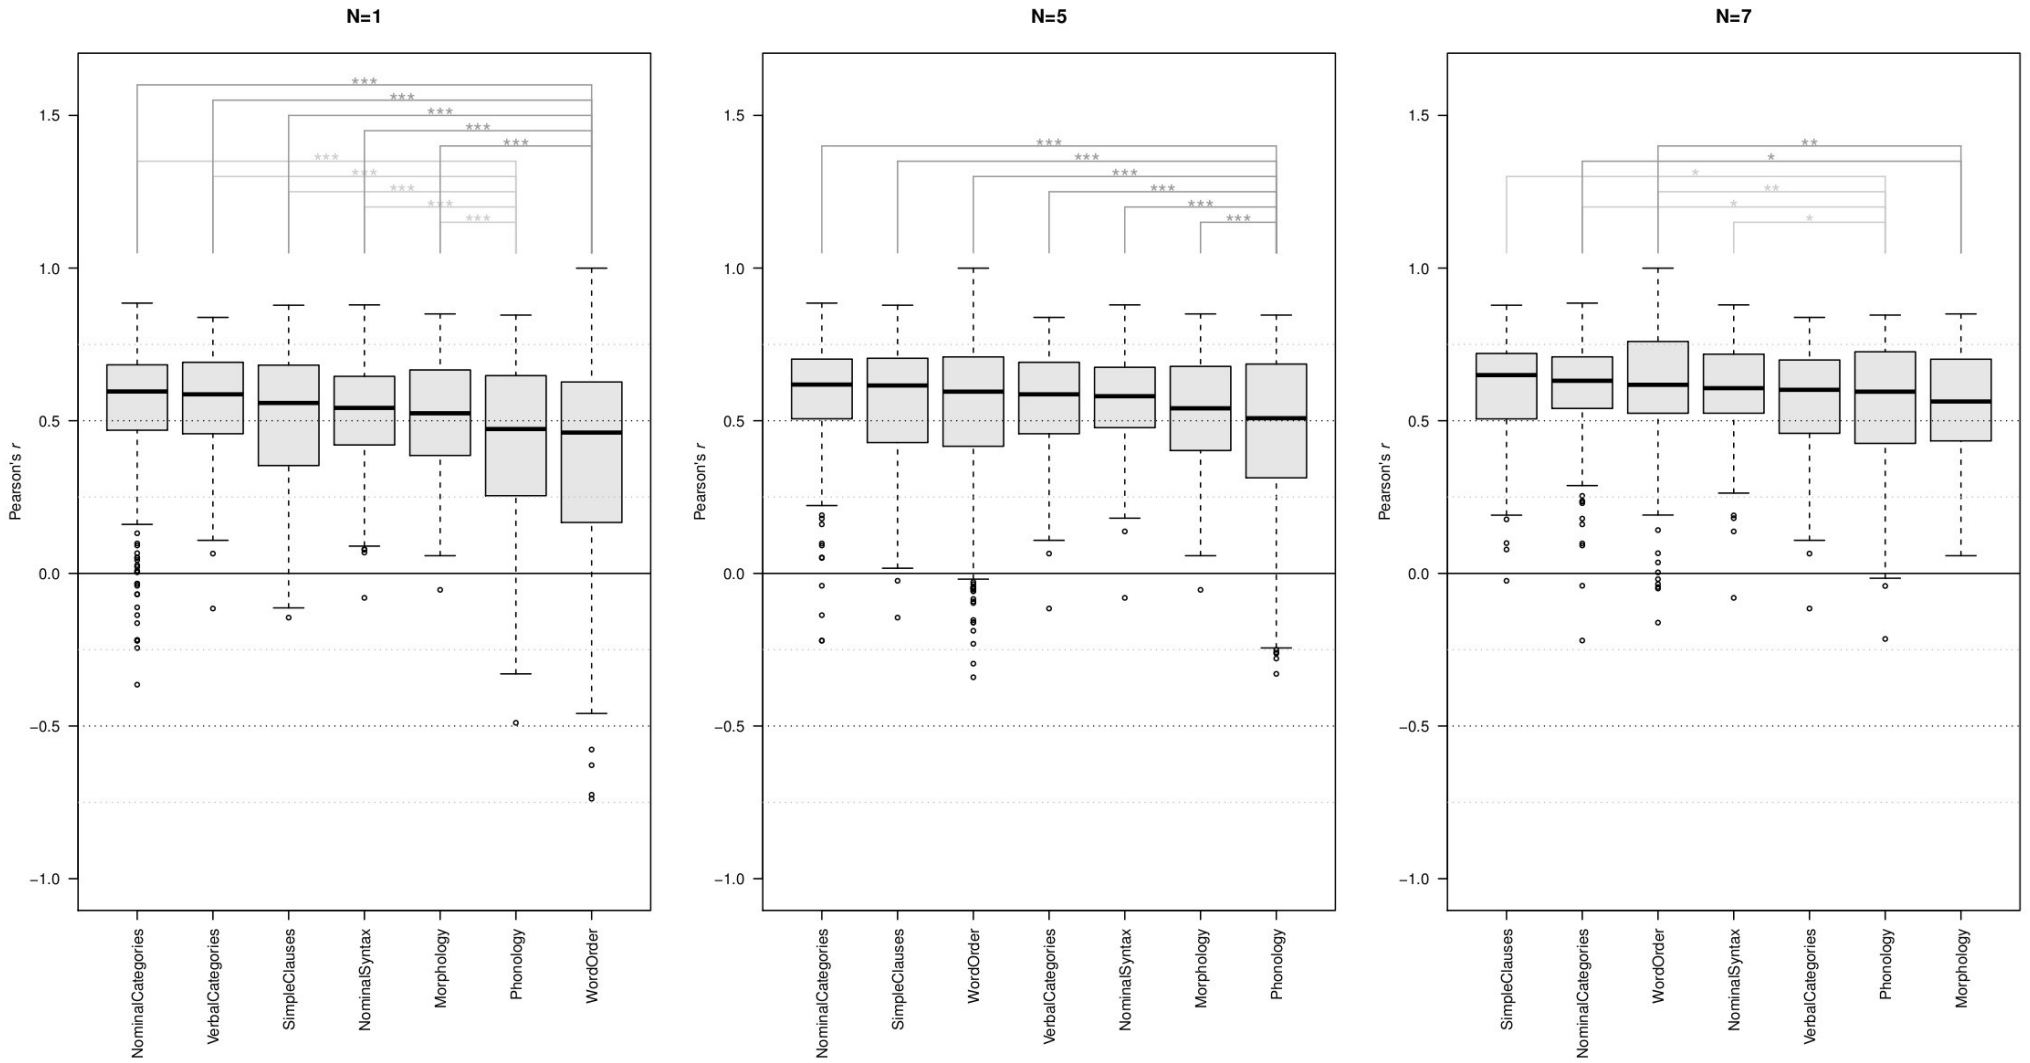

***Figure S16**: Boxplots of the correlation (Pearson's r) between branch length and number of nodes for each category across 4 datasets (MBH, MPH, BBH and BPH) and all outgroups. The categories are ordered from highest median correlation (left) to the lowest (right) Shown are the boxplots for all families with data for at least one (N=1), five (N=5) or all (N=7) categories of features. Shown are also the significant pairwise differences (corrected using Tukey's HSD) between categories (different shades of grey are for visual effect only; alpha levels are signified as *=0.05, **=0.01, ***=0.001).*

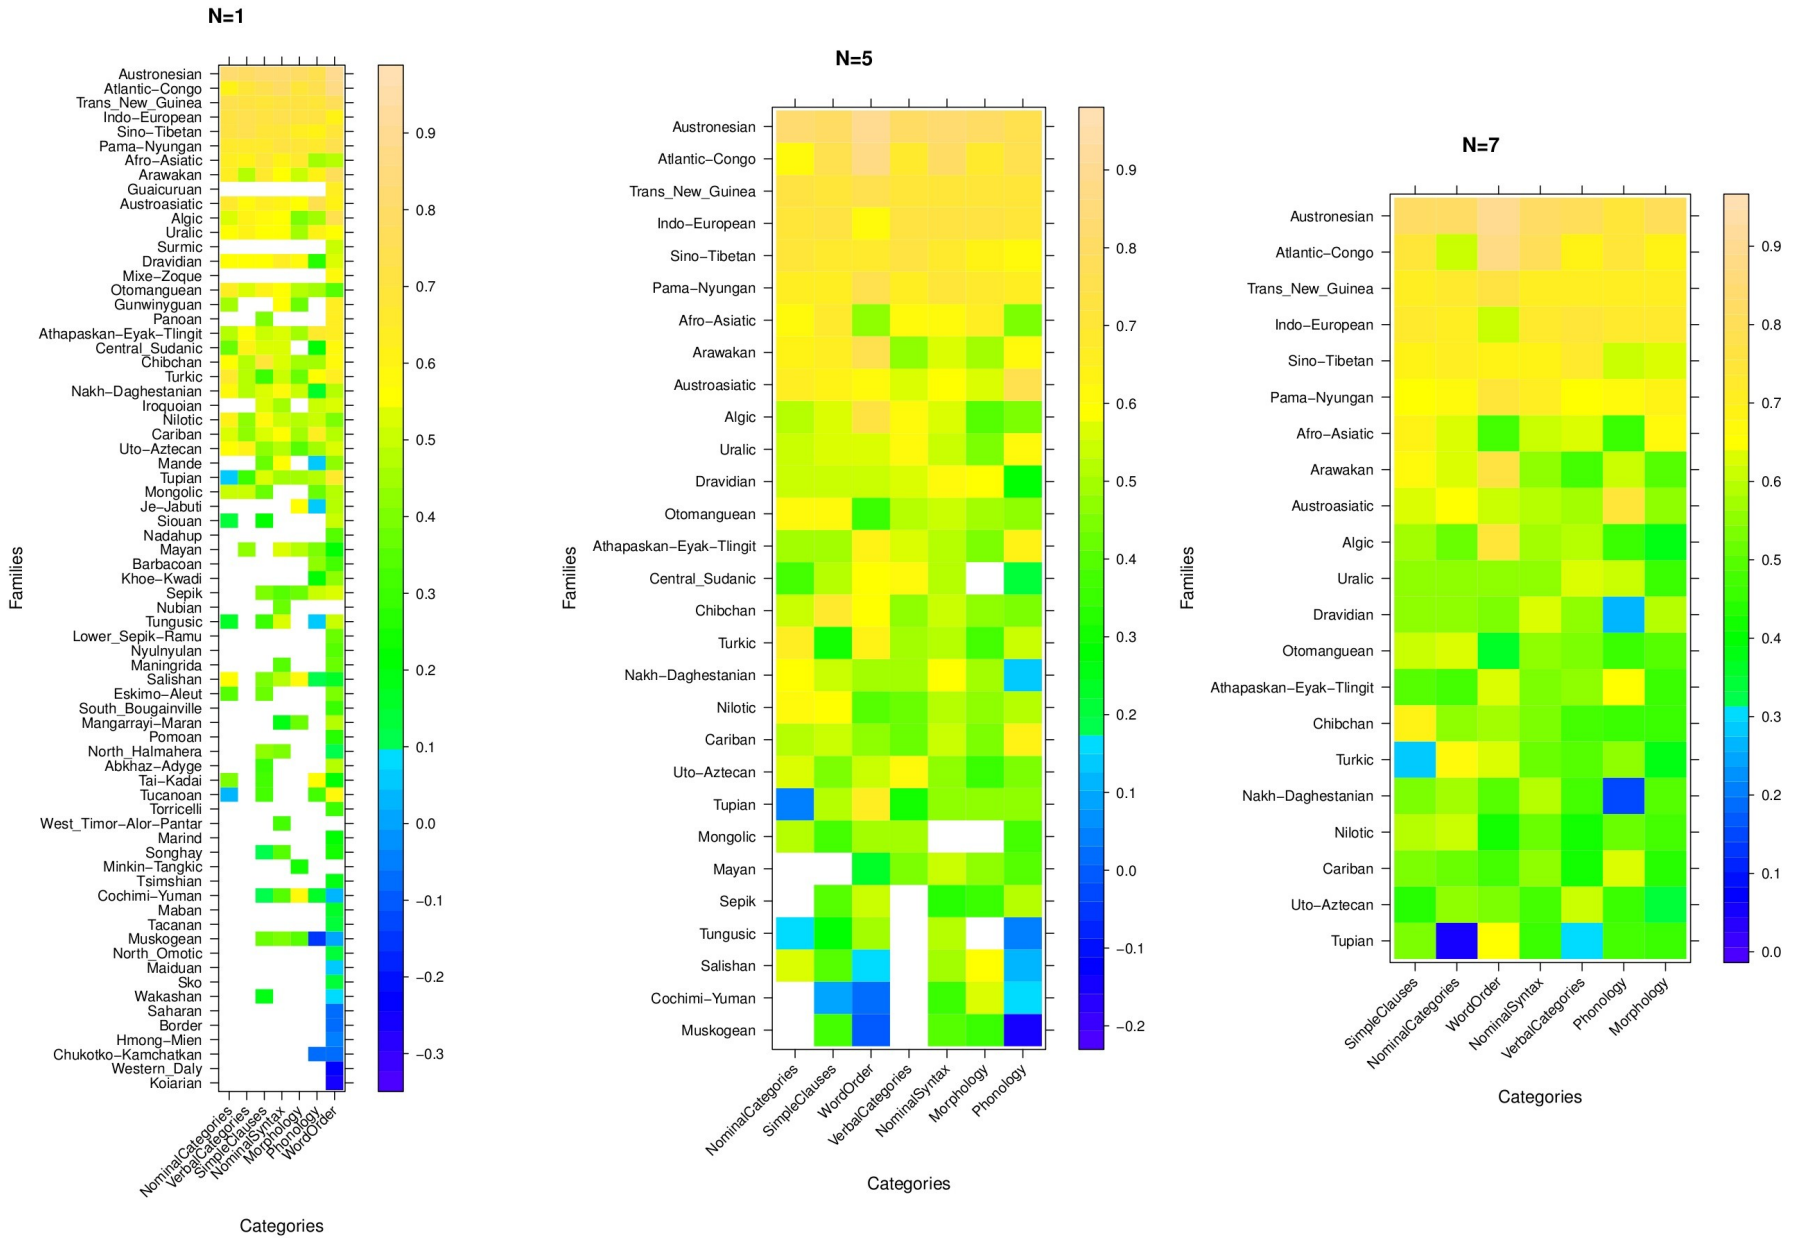

Figure S17*: Intensity plots of the mean correlation (Pearson's r) between branch length and number of nodes for each category and family across 4 datasets (MBH, MPH, BBH and BPH) and all outgroups. The categories are ordered from highest mean correlation (left) to the lowest (right), and the families from top to bottom. Shown are the boxplots for all families with data for at least one (N=1), five (N=5) or all (N=7) categories of features.*

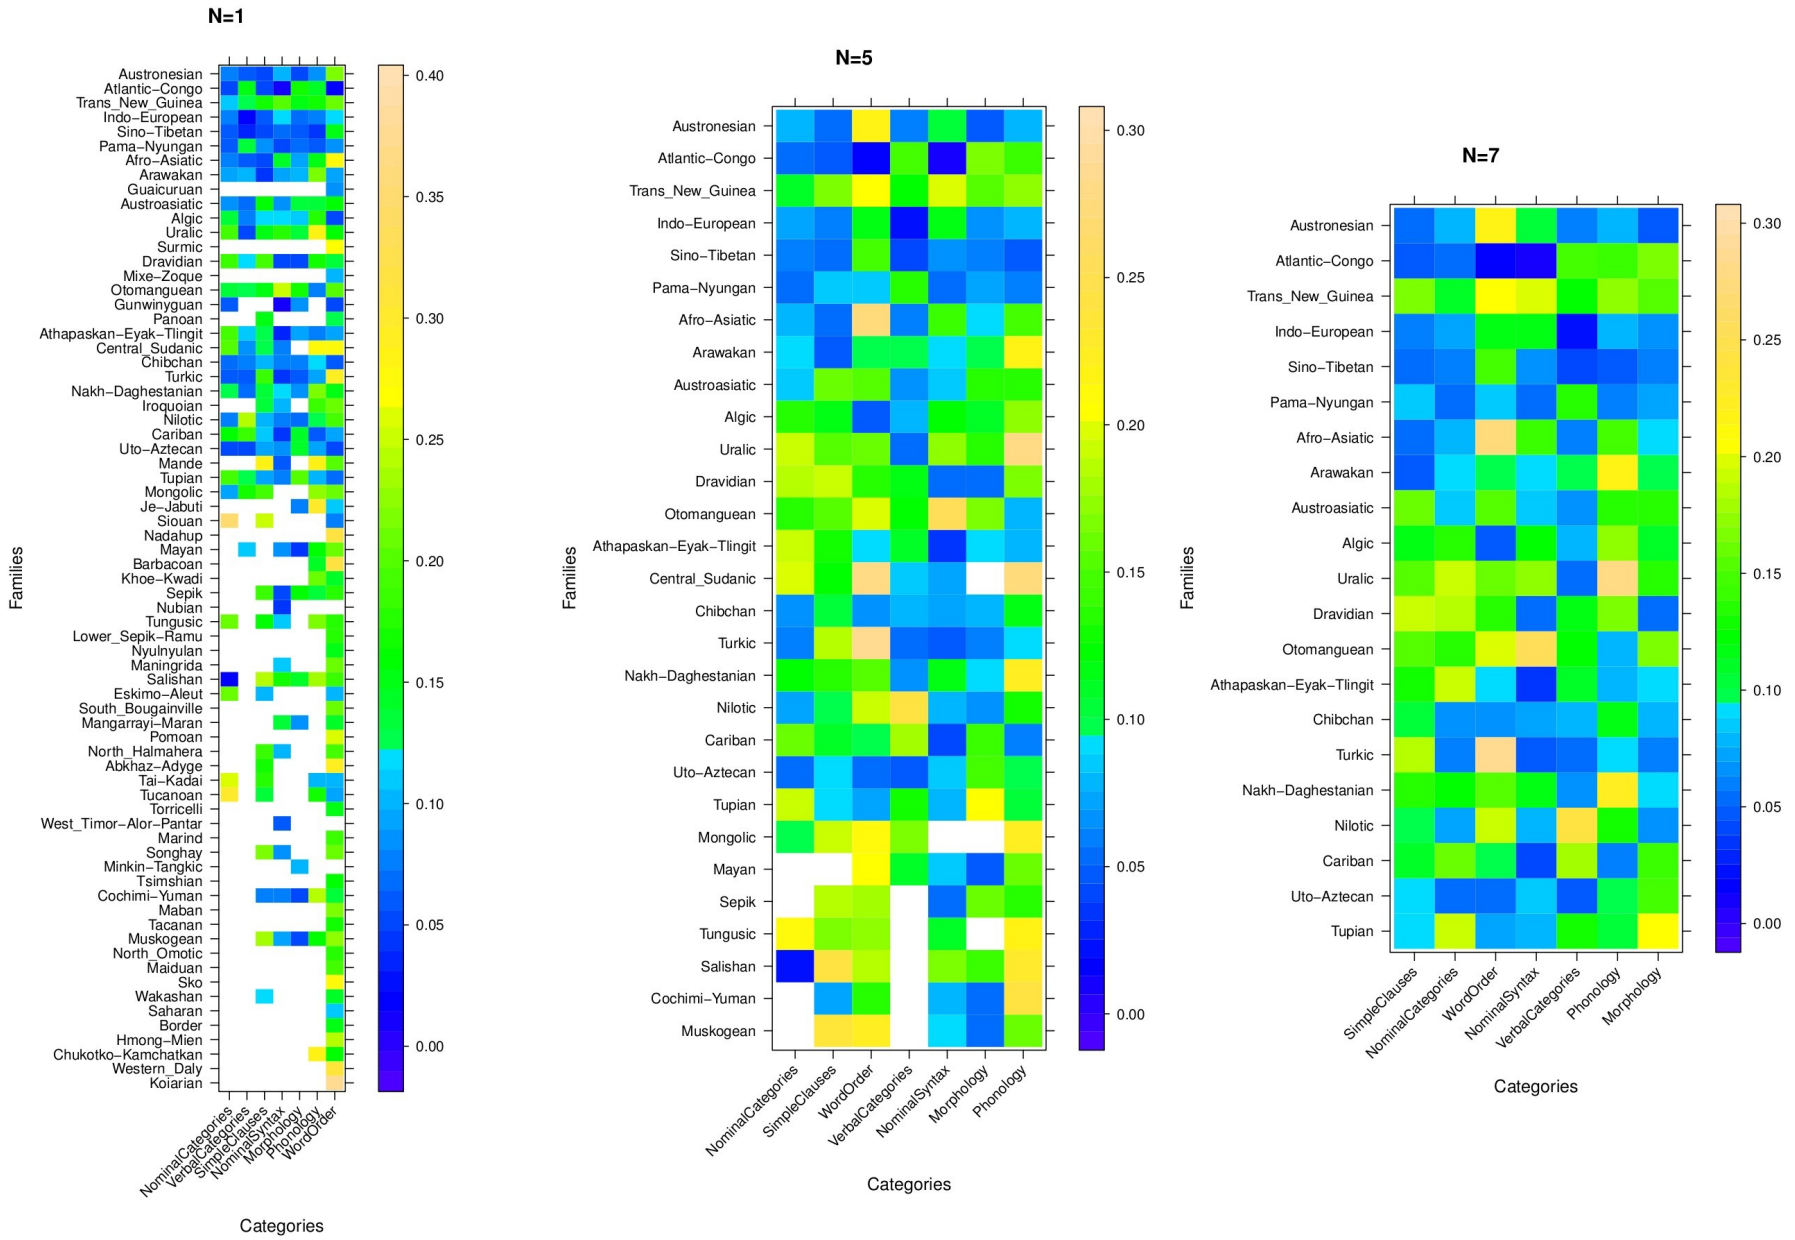

Figure S18: *Intensity plots of the standard deviation of correlations (Pearson's r) between branch length and number of nodes for each category and family (see Figure S17 for details).*
