Supplementary Results

a)
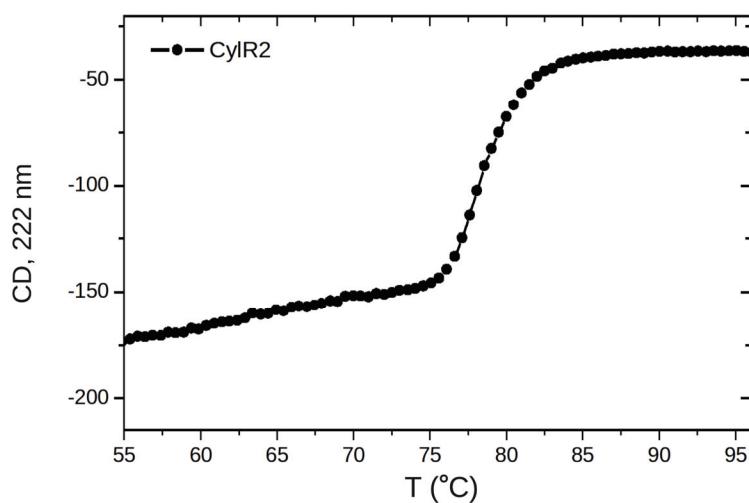

b)
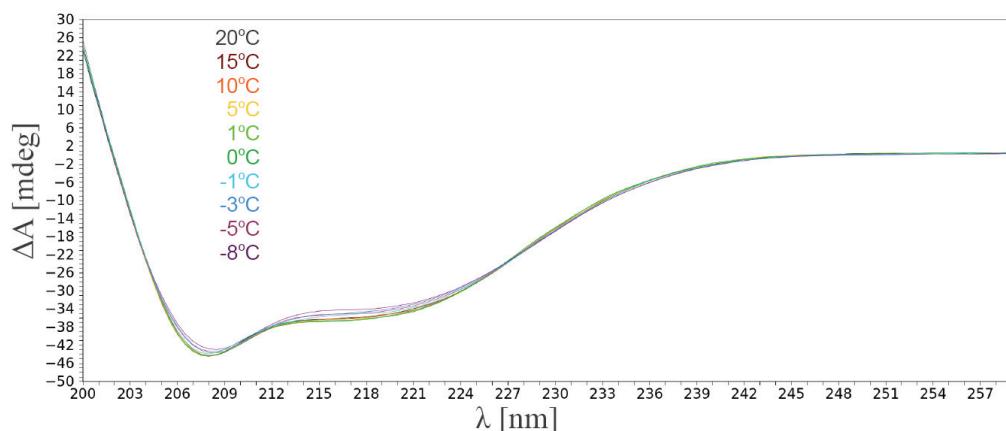

Supplementary Fig. 1. Analysis of secondary structure of CylR2 by circular dichroism. (a) Melting curve of CylR2 monitored at 222 nm (from a single measurement). The midpoint of heat denaturation is 77.5 °C. (**b**) Influence of decreasing temperatures. Below 0 °C small changes were observed at 208 nm and 214-220 nm consistent with the solved 3D structures (**Fig. 4**) that revealed the destabilization of the short (6 residues) terminal β-sheet with decreasing temperatures while the helical structure was preserved. Temperatures below -8 °C could not be reached due to limited stability of the CD instrument.

Supplementary Fig. 2. Graphical representation of backbone ^{15}N-^{1}H (**a**) and ^{15}C$^{\alpha}$-^{1}H$^{\alpha}$ (**b**) cross-peaks that are no longer observable at decreasing temperatures.
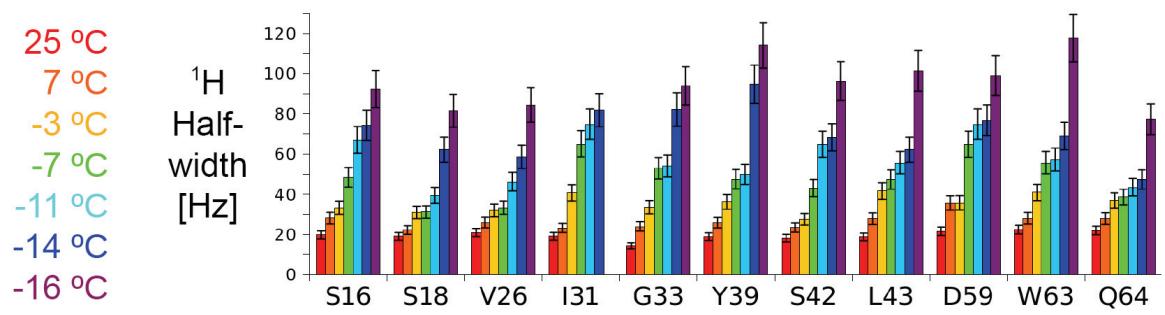

Supplementary Fig. 3. Increase in amide proton line widths at low temperatures due to the interconversion between different conformations at an intermediate exchange rate.
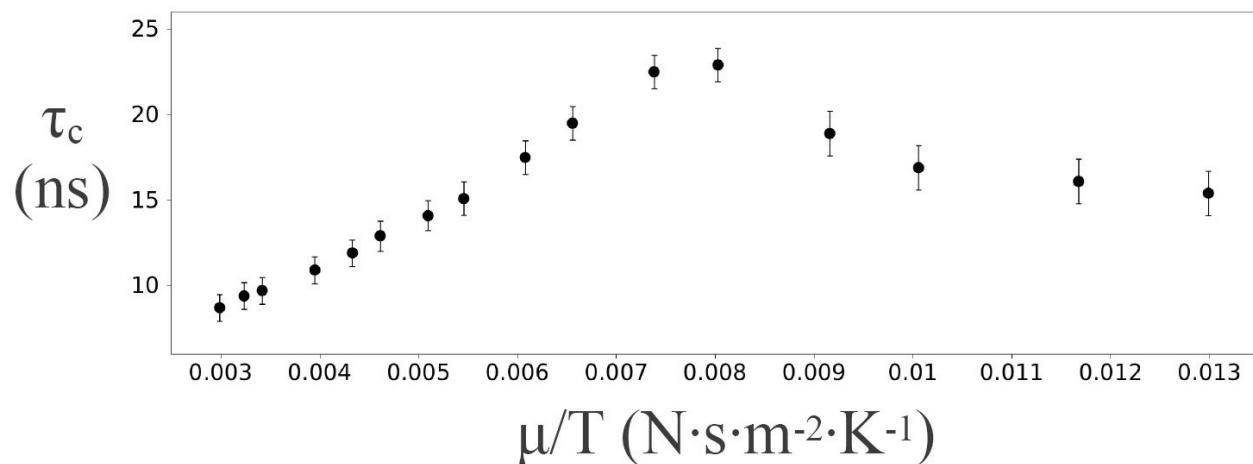

Supplementary Fig. 4. Relation between the global correlation time of CylR2, τ_c, and the dynamic viscosity of water $\eta(T)$ divided by the temperature of the measurement. Values of the dynamic viscosity of water were taken from http://www.engineeringtoolbox.com/water-dynamic-kinematic-viscosity-d_596.html and Hallett [1].
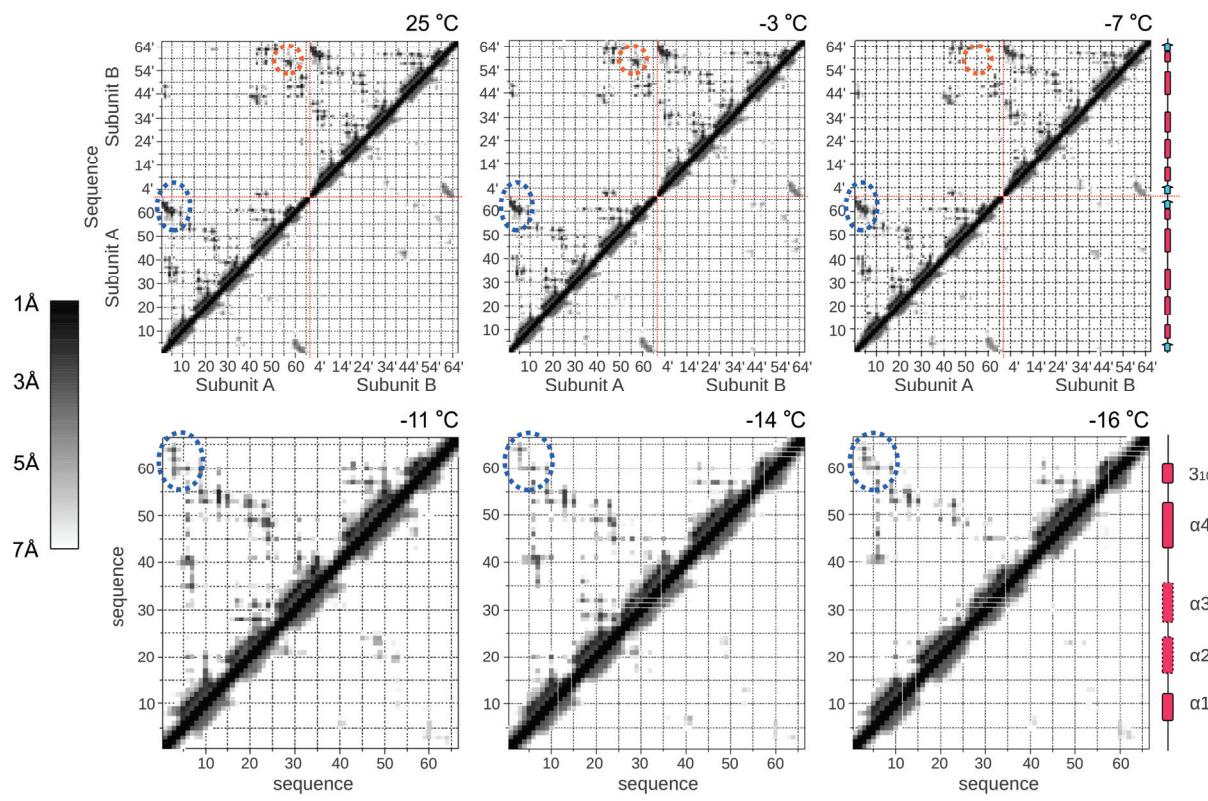

Supplementary Fig. 5. Contacts plots of CylR2 structures at different temperatures. The upper-left and lower-right parts indicate inter-proton and inter-heavy atom contacts, respectively. The three upper panels present the dimeric and the three lower panels the monomeric species. Secondary motifs are depicted on the right edge of the panel row. Red dashed circles highlight the symmetrical inter-subunit interactions between Pro56Leu57Glu58 fragments, which disappear at -7°C. The blue dashed circle marks the hydrophobic interactions between the C- and N-terminal parts of CylR2 that partially remain despite the loss of the four H-bonds stabilizing the anti-parallel β-strands of CylR2.
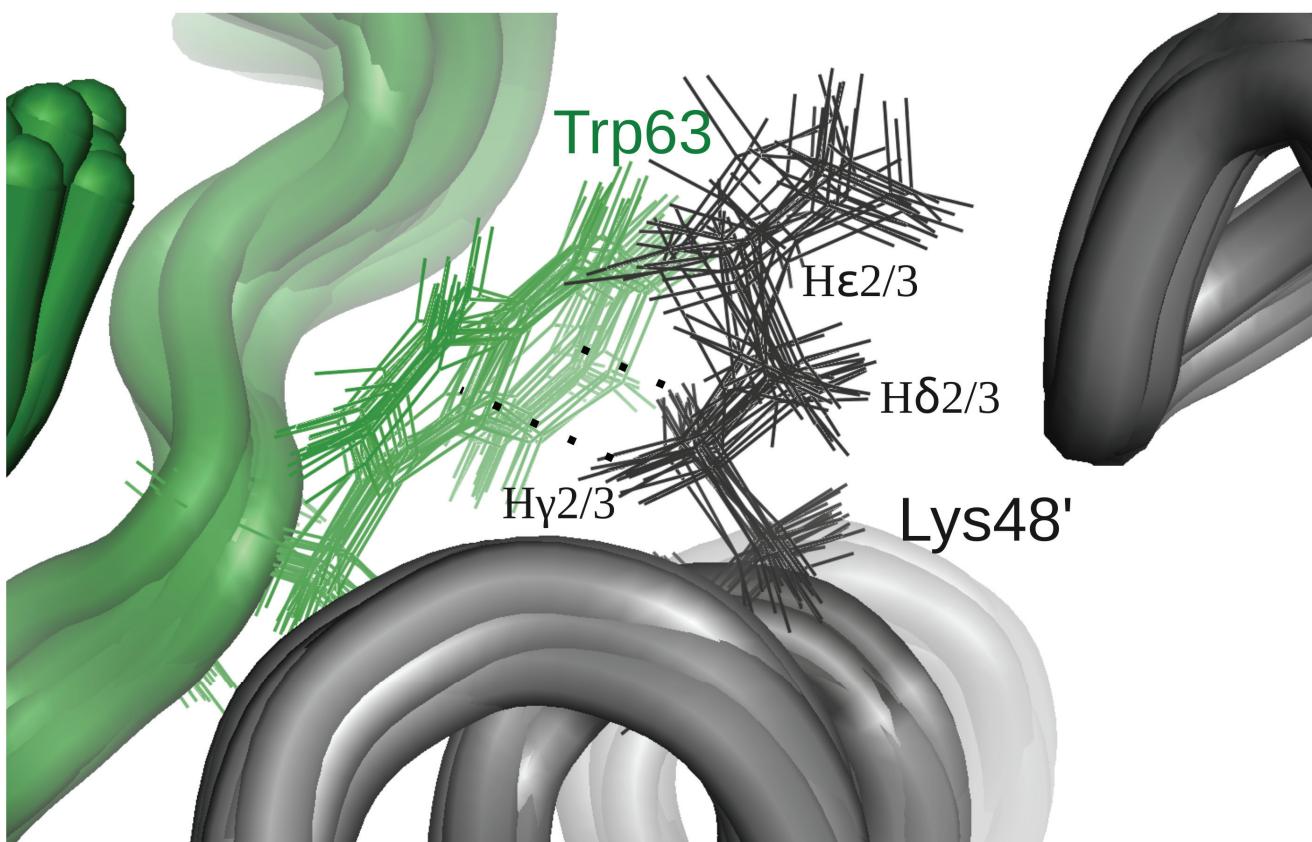

Supplementary Fig. 6. Expanded small region of the NMR ensemble of CylR2 at 25 °C highlighting the intermolecular C-H···π interaction between the aromatic moiety of Trp63 and the Hγ2/3 side chain protons of Lys48. The black dotted line is drawn from the side chain proton of Lys48 in subunit 1 (black) to the center of the aromatic moiety of Trp63 in subunit 2 (green).
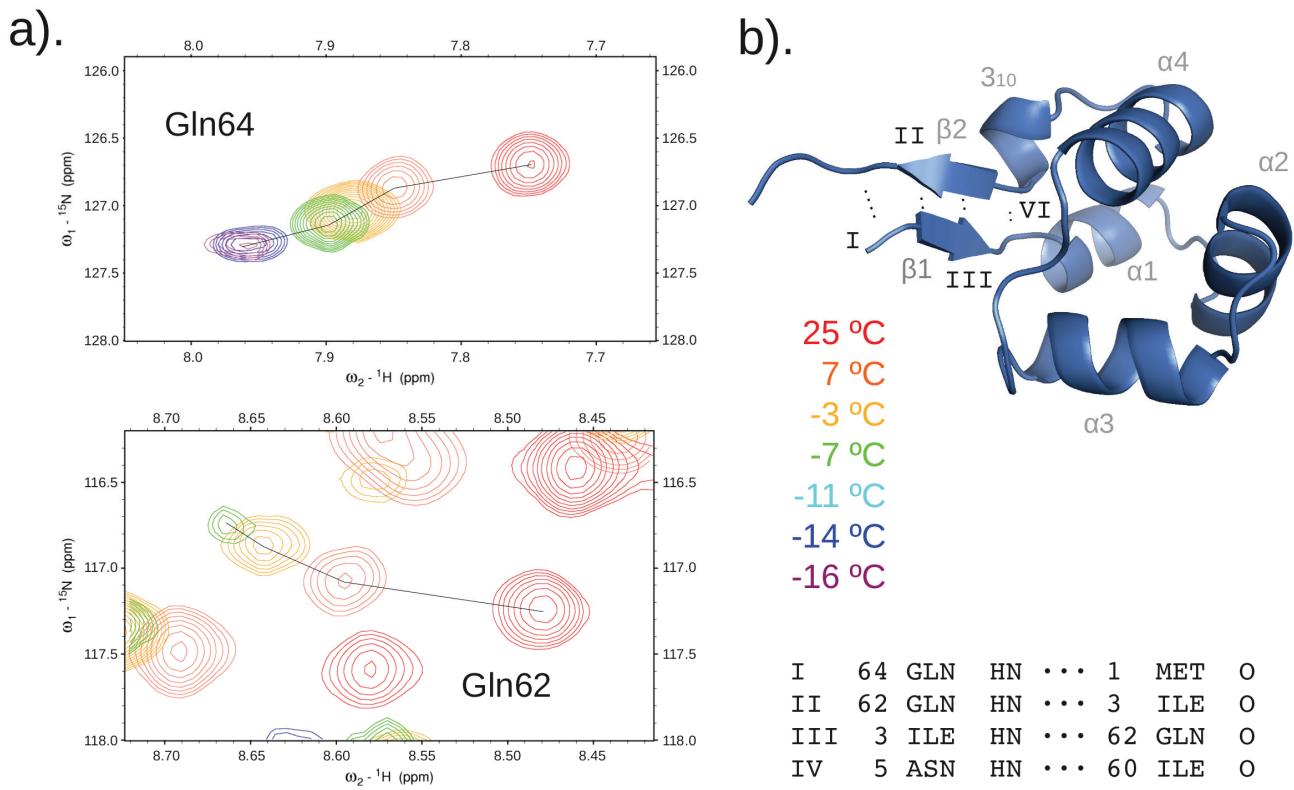

Supplementary Fig. 7. (a) Selected regions from 2D [^{1}H,^{15}N] HSQC spectra at different temperatures highlighting the non-linear temperature dependence of amide protons of Gln62 and Gln42. (b) H-bonds that stabilize the N and C-terminal β-strands at the temperatures above -7 °C.
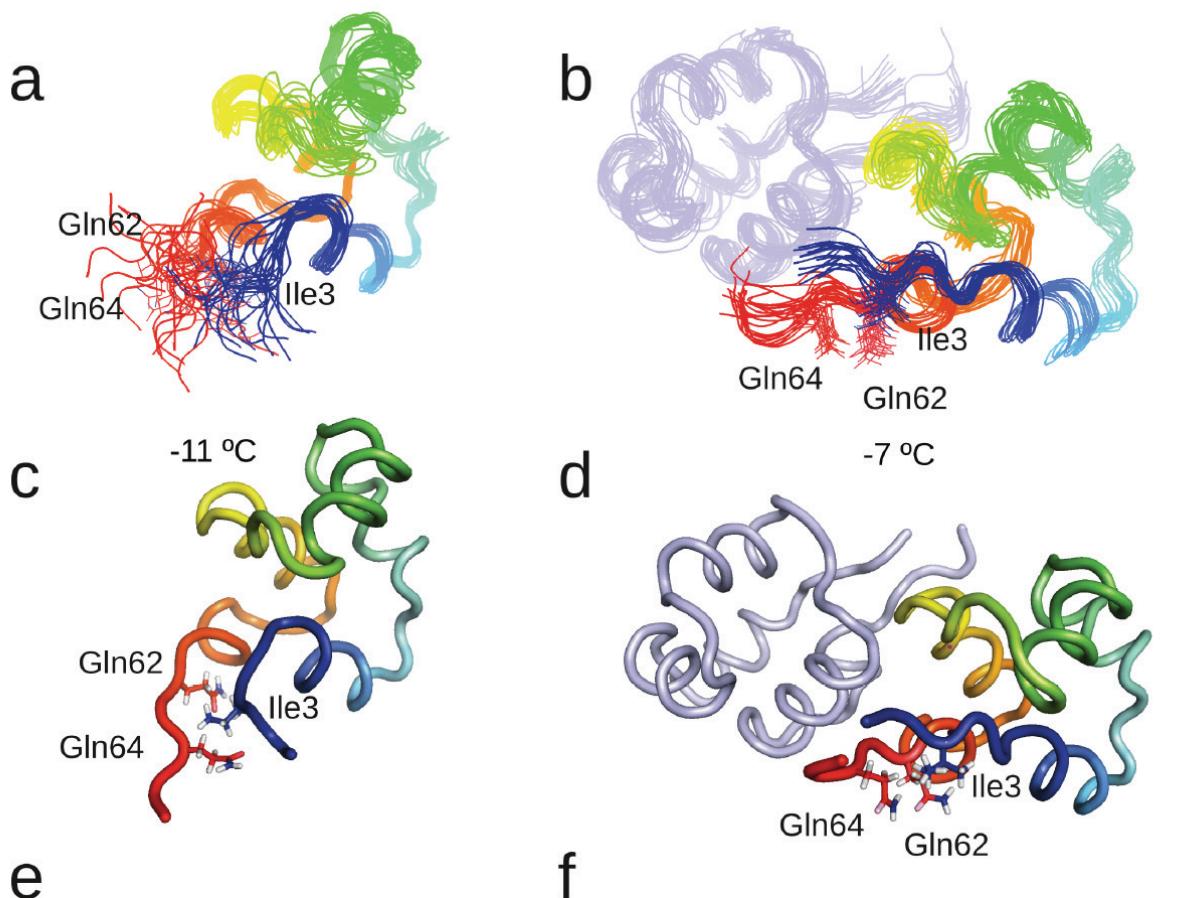

Supplementary Fig. 8. Mechanism of unfolding of the intramolecular β-sheet of CylR2. Backbone representations of the NOE-based structures of CylR2 determined at -11 °C **(a and c)** and at -7 °C **(b and d)**. The side chains of residues that keep the native contacts between the two antiparallel β-strands in the predissociated dimer (structure at -7 °C) and in the monomeric intermediate (structure at -11 °C) are drawn as sticks. **(e)** and **(f)** highlight specific contacts between these residues observed in 3D ^{13}C-edited NOESY-HSQC spectra at -11 °C and -7 °C, respectively. Despite the strong destabilization of the backbone of the β-sheet native-like contacts of the side chains.
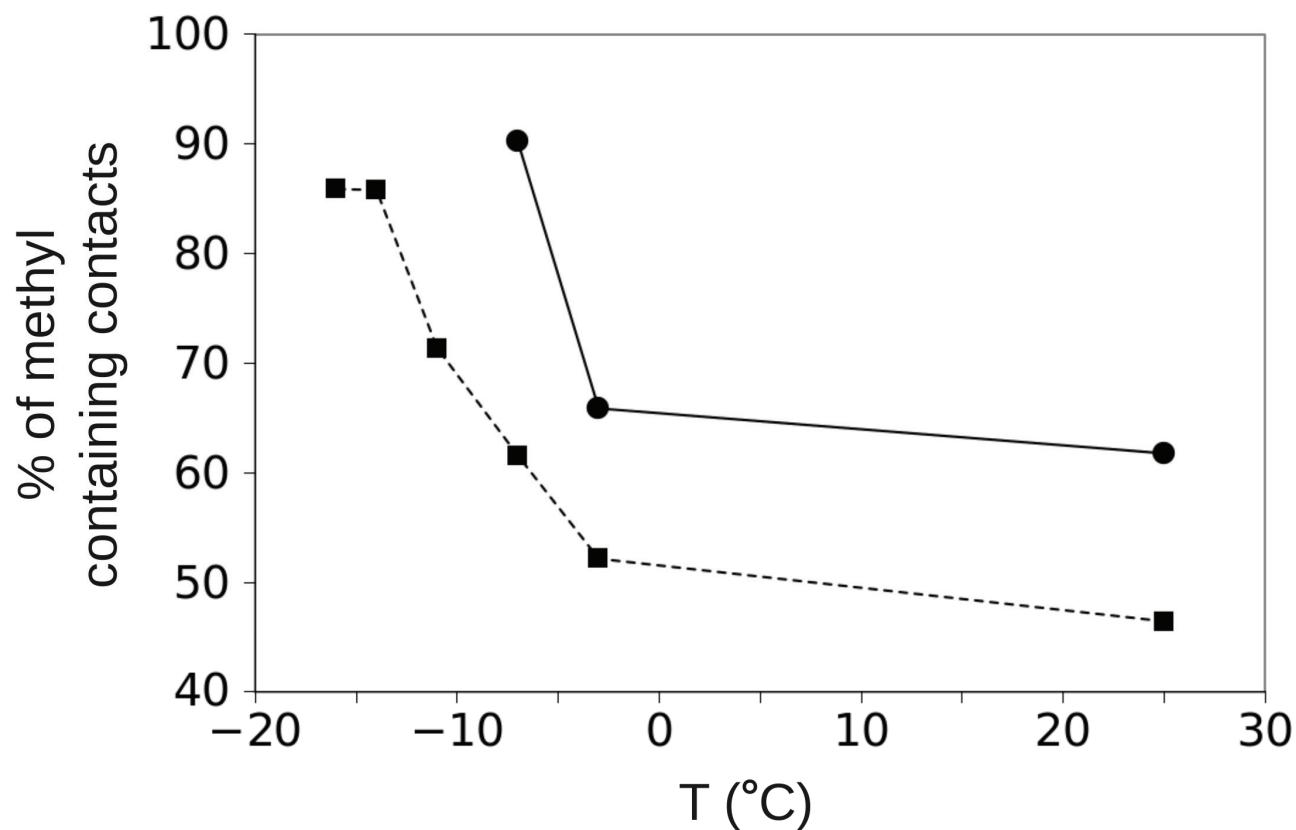

Supplementary Fig. 9. Fraction of methyl-containing NOE contacts at different temperatures within a CylR2 monomer (dashed line) and between the two molecules of the CylR2 dimer (solid line).
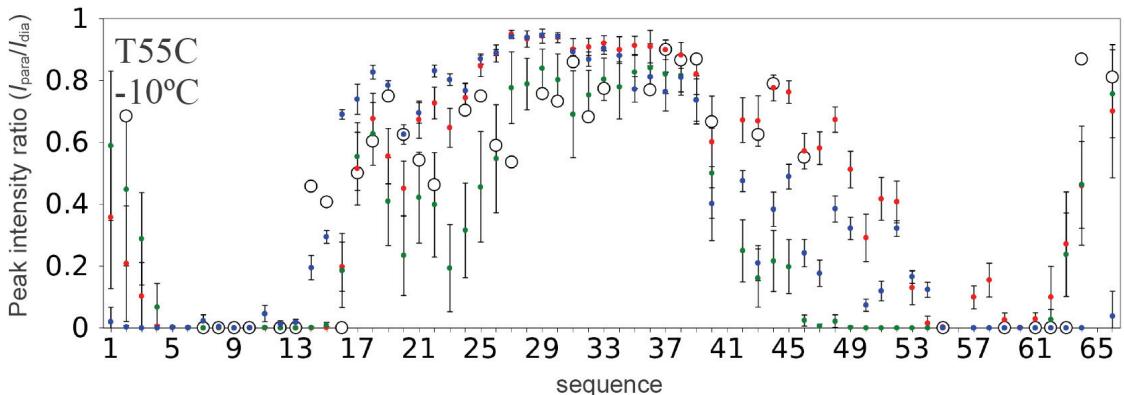

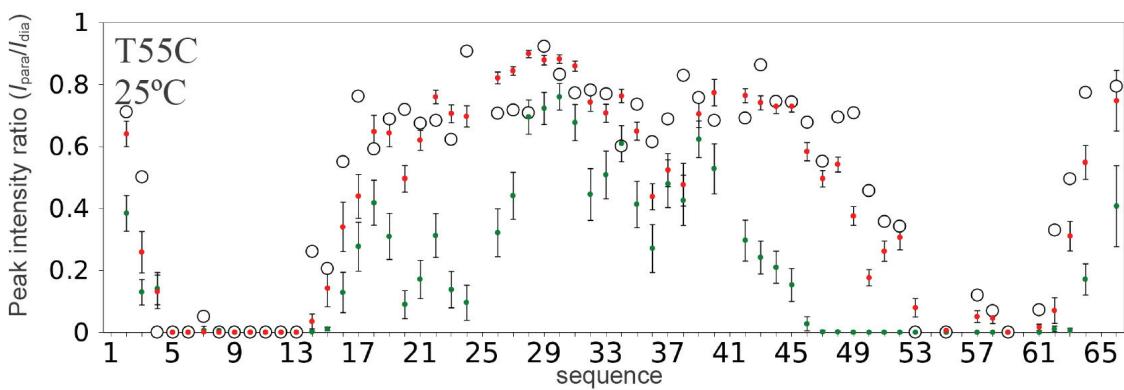

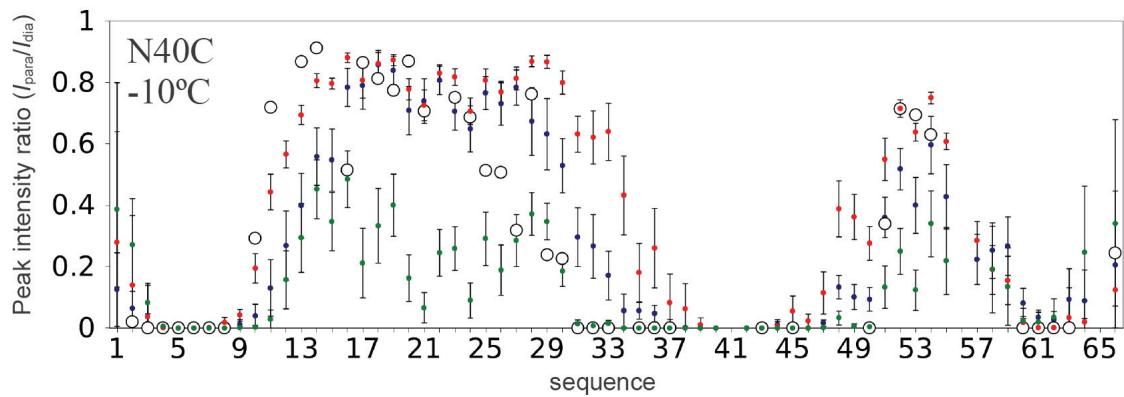

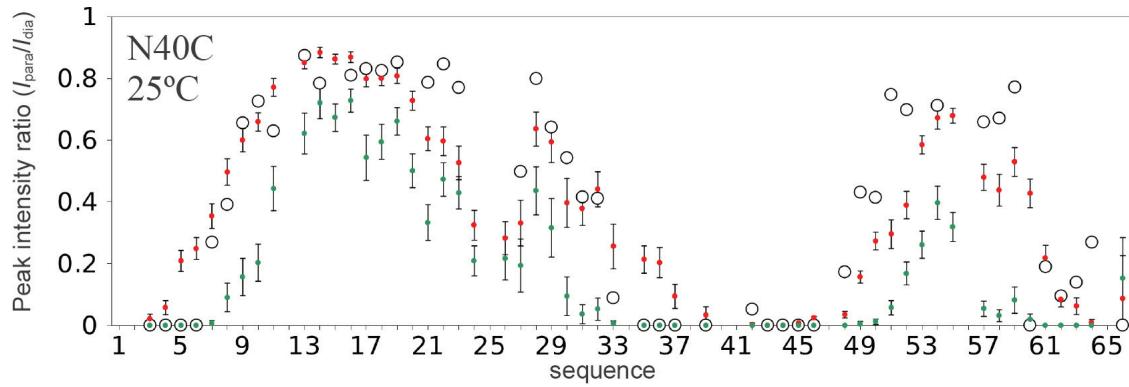

Supplementary Fig. 10. Comparison of experimental PRE profiles with values predicted from 3D structures of CylR2 during cold-denaturation. In the upper two panels results for N40C MTSL-tagged CylR2 are shown. In the lower two panels the results for T55C MTSL-tagged CylR2 are presented. Experimental PRE profiles are shown as open circles and were recorded at 25 °C and -10 °C. Green points mark the theoretical profiles predicted by positioning the paramagnetic center at the Cβ atom of N40 (upper two panels) and T55 (lower two panels). The red profiles were predicted when the paramagnetic center was located at the oxygen of a MTSL molecule that was attached to cysteine 40 and 55, respectively. Blue profiles are from MTSL positions rotated by ~180° around the S-S bond between cysteine and MTSL. Error bars for predicted profiles represent ± 1 standard deviation from the linear average of 20 predicted profiles within the ensemble of 20 conformers at each temperature. Averaged errors from three measurements for experimental PRE intensities are 0.11 for N40C at -10 ^{o}C, 0.10 for N40C at 25 ^{o}C, 0.08 for T55 at -10 ^{o}C and 0.06 for T55C at 25 ^{o}C. The comparison of the experimental PRE data with predicted values highlights the impact of the exact position of the paramagnetic center and therefore the conformation of the MTSL side chain for prediction of PRE values from a 3D structure.
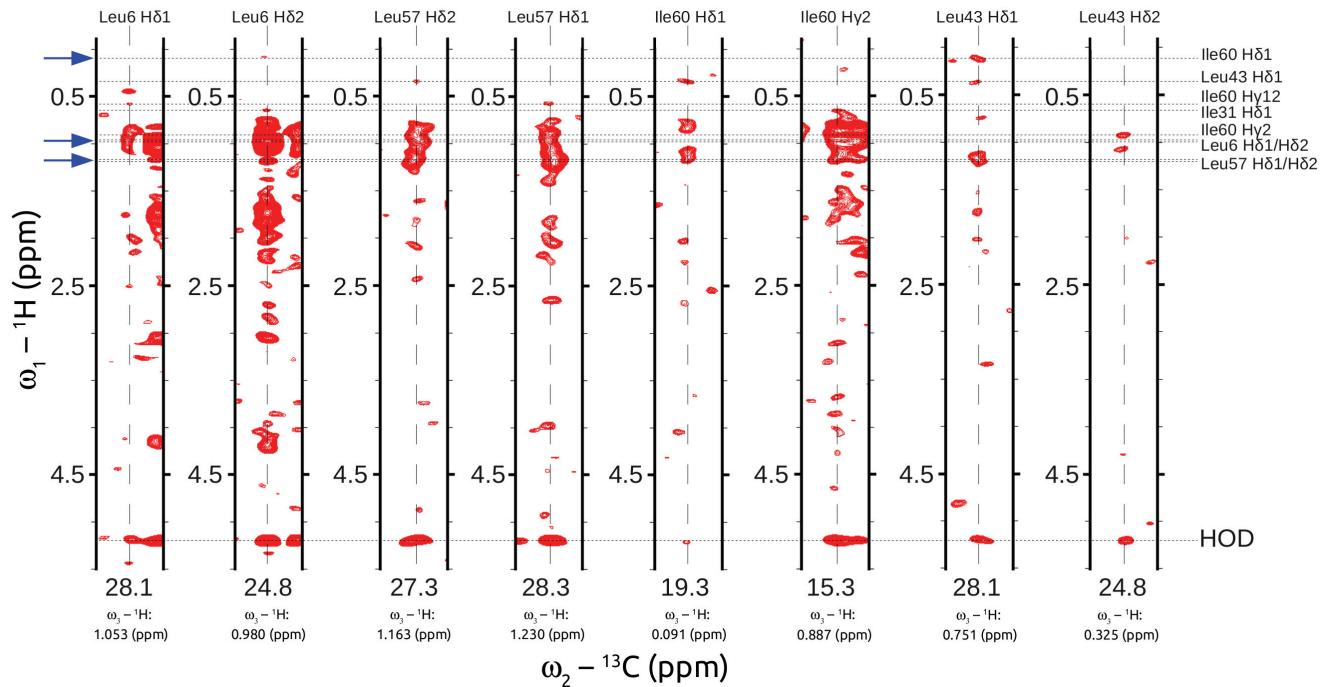

Supplementary Fig. 11. Strips from the 3D ^{13}C-edited NOESY-HSQC spectrum at -11 °C demonstrating the presence of non-native contacts between Ile60, Leu57, Leu43 and Leu6 (indicated by blue arrows) in the monomeric intermediate.

Supplementary Fig. 12. Effect of the point mutations L6S (left column) and I49S (right column) on CylR2. (a) Superposition of 2D [^{1}H,^{15}N] HSQC spectra for mutant (red) and wild-type (WT) protein (blue). (b) Normalized and averaged ^{1}H/^{15}N chemical shift differences of backbone amide resonances in mutant CylR2 with respect to the wild-type form. The error in $\Delta\delta$ is 0.05 ppm. (c) 2D [^{1}H,^{13}C] NOESY planes of L6S and I49S mutant CylR2 highlighting the strongly shifted side chain chemical shifts of the K48 side chain due to the presence of intersubunit C-H⋯π interactions between the aromatic moiety of Trp63 and the Lys48 side chain. (d) Steady-state ^{15}N-^{1}H NOE values at 25 °C for mutants and (e) their difference plots against wild-type CylR2. f) Difference plots between Cα chemical shifts of mutant and wild-type CylR2. The secondary motifs are preserved in both mutants. The maximum error is 0.2 ppm.
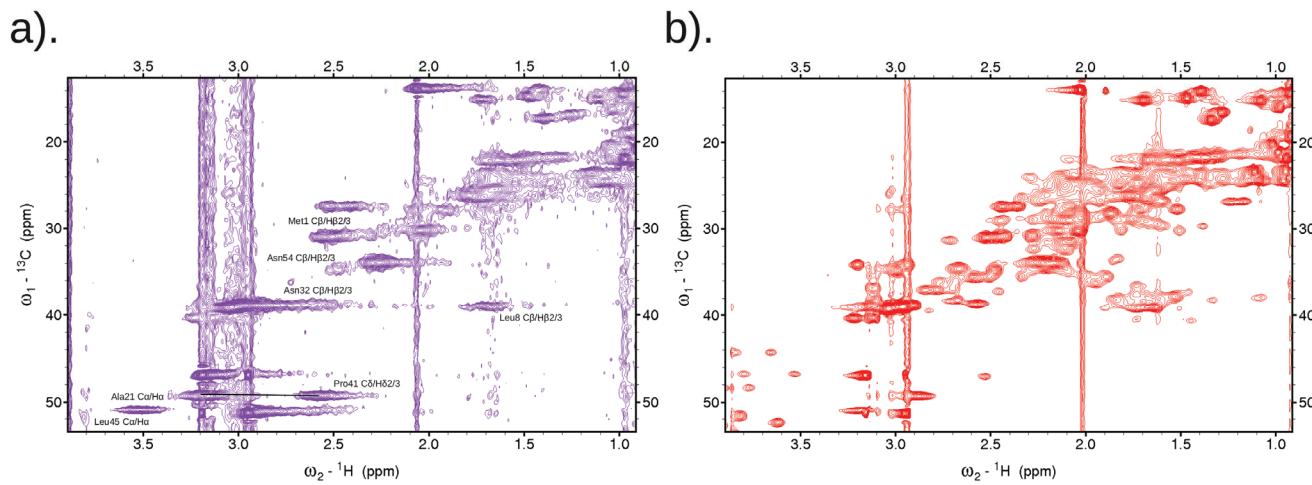

Supplementary Fig. 13. Selected region of 2D [^{1}H,^{13}C] HSQC spectra of cylR2 at -16 °C (a) and 25 °C (b). Selected Cα/Hα and side chain resonances are labelled.
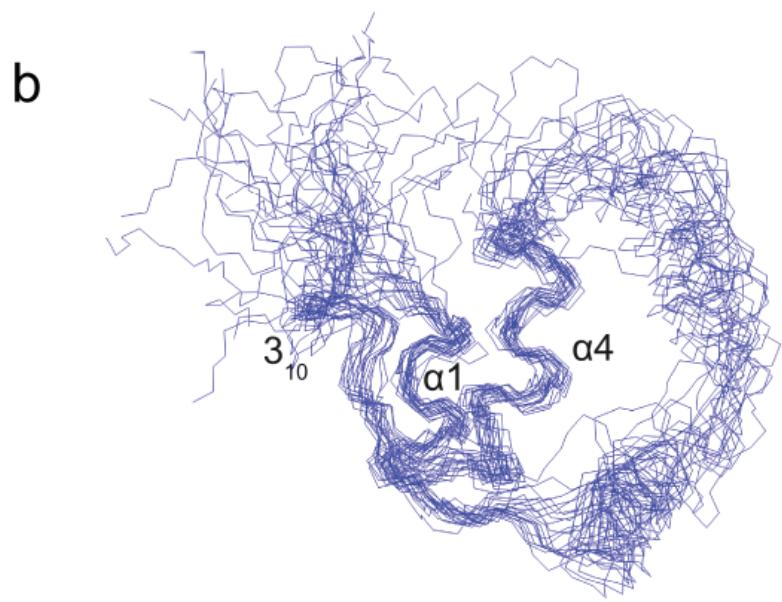

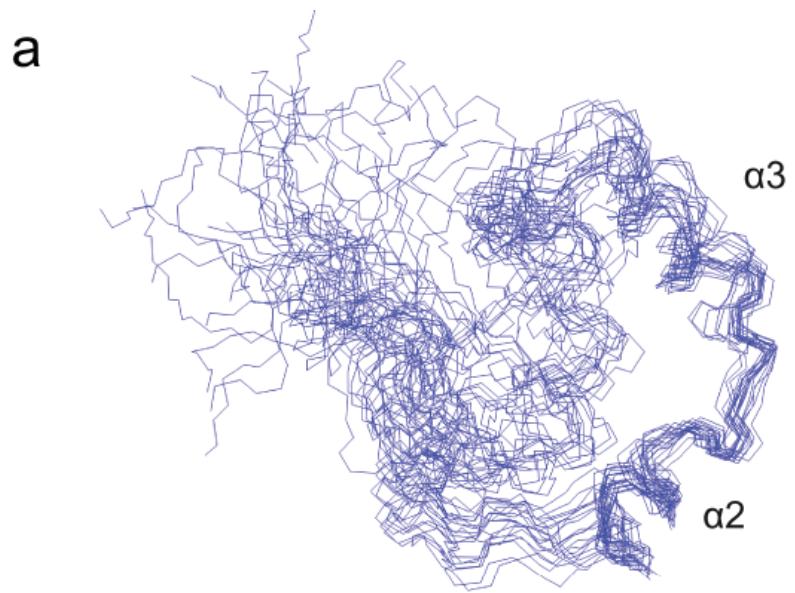

Supplementary Fig. 14. Ensemble of conformers of the partially folded monomeric intermediate at -16 °C using different subdomains for superposition. **(a)** The helix-turn-helix motif was used for alignment. **(b)** Helices $\alpha 1$, $\alpha 4$ and 3_{10} were used for alignment.
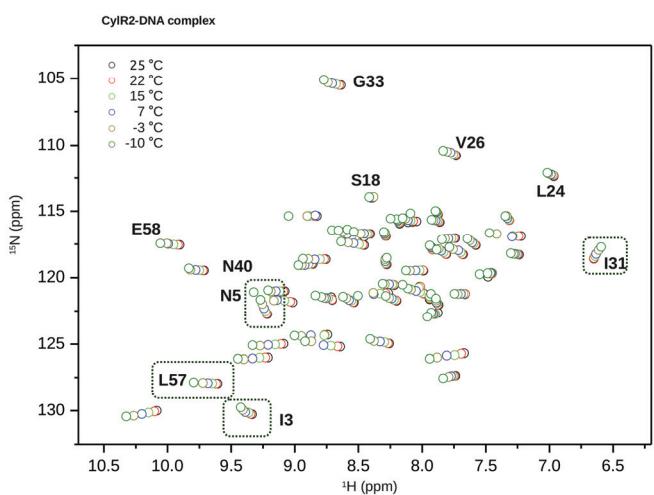

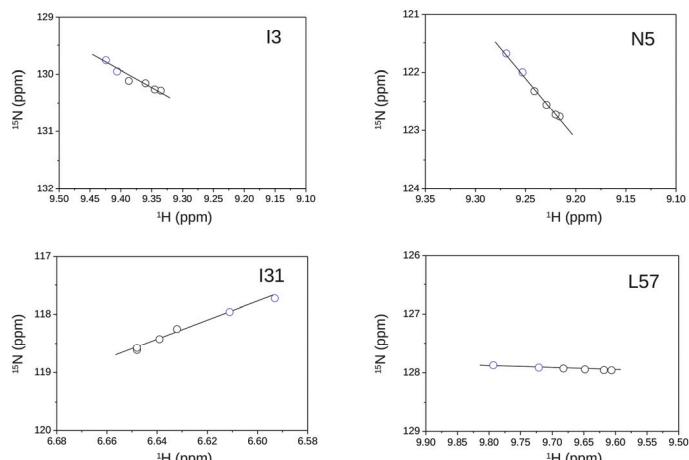

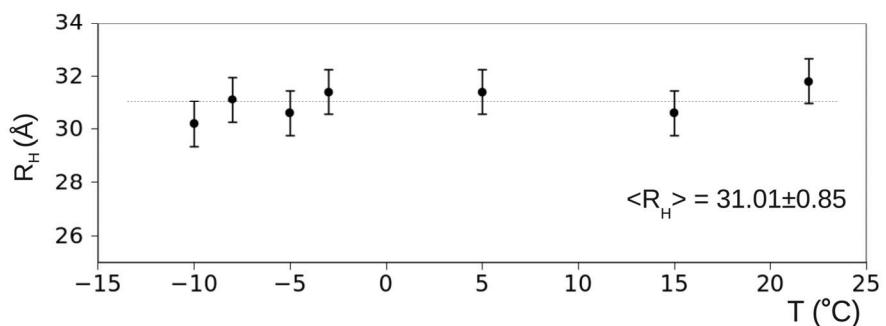

Supplementary Fig 15. Temperature dependence of the CylR2-DNA complex. a) 2D [^{1}H,^{15}N] TROSY-HSQC spectra as a function of temperature. b) 2D chemical shift plots for selected residues demonstrating a linear chemical shift dependence for decreasing temperature. c) Hydrodynamic radius (R_h) as a function of temperature. The averaged hydrodynamic radius (dotted line) $\langle R_h \rangle$ = 31.01±0.85 Å of the CylR2-DNA complex remains unchanged along the studied temperature range within the experimental error.
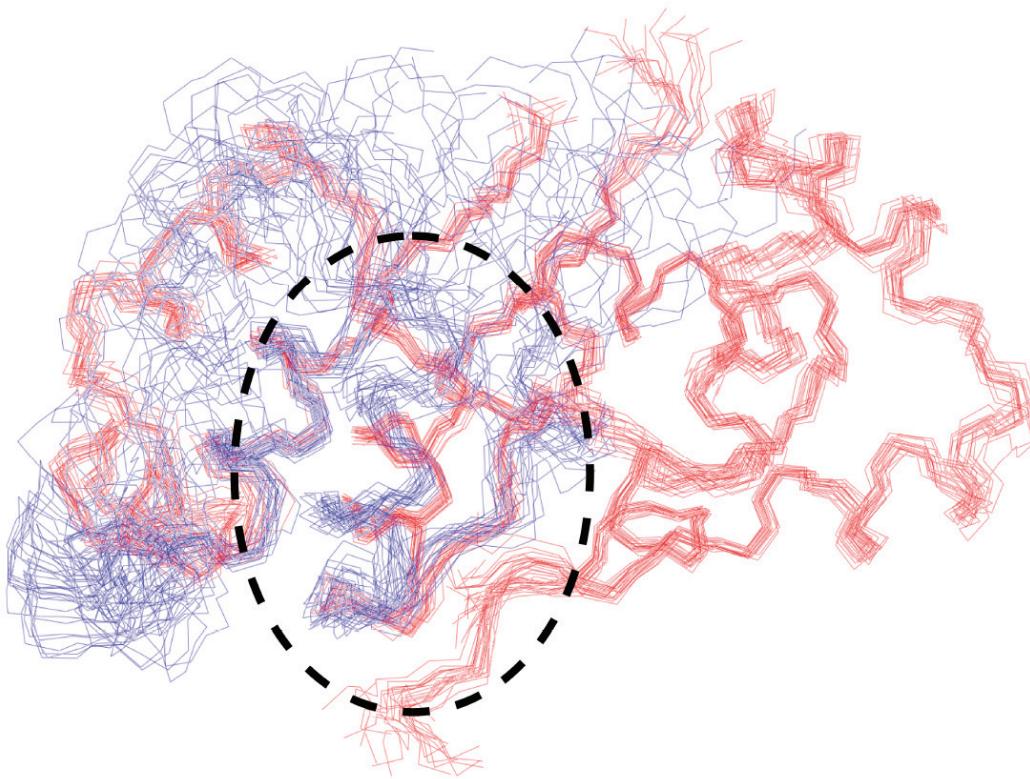

Supplementary Fig 16. The core of the partially folded intermediate forms the dimer interface in the native state. Superposition of the NOE-based ensemble of conformers at -16 °C (blue) and the native CylR2 dimer determined at 25 °C (red). The superimposed fragments consist of Leu6 - Ile15 and Leu43 - Ile60 marked by an ellipse. The two α-helices (α1 and α4) and one 3_{10}-helix form the folding nucleus that predisposes the protein for dimerization.

Supplementary Table 1 | Simulation of the effect of changes in the global correlation time (tau_c) and in the time scale (tau_i) and amplitude (S^2) of internal motions on ^{15}N-^{1}H NOE values. Changes in global correlation time are due to the temperature-dependence of solution viscosity (increase from 25 °C to 5 °C) and due to the dissociation of the CylR2 dimer into a monomer at -11 °C. Calculations have been done using Lipari-Szabo's correlation functions assuming a nearly isotropic global motion and fast internal motions that are separable from global motion [2,3].

a) For the ensemble calculations at -7 C°, which used an equal mixture of dimeric and monomeric forms, XPLOR-NIH was modified.

b) Evaluated for 20 lowest energy structures out of a total 200 calculated structures.

Supplementary Table 4 | Distances averaged for conformers of CylR2 ensembles determined at different temperatures.

Temperature (°C)	Cγ – Cζ'	Cα – Cα				
	P65-Y51'	L57-L57'	L6-I60	L6-I49	L6-I31	L6-L24
25	4.0 ± 0.4	7.1 ± 0.3	5.1 ± 0.1	8.2 ± 0.1	8.9 ± 0.3	12.9 ± 0.5
-3	8.8 ± 1.1	6.7 ± 0.4	5.2 ± 0.2	8.0 ± 0.2	9.0 ± 0.3	13.1± 0.7
-7 (dimer)	11.9 ± 2.1	10.2 ± 0.9	4.4 ± 0.3	8.6 ± 0.3	8.8 ± 0.4	13.1 ± 0.5
-7 (monomer)	N/A	N/A	4.9 ± 0.6	8.7 ± 0.3	8.7 ± 0.3	12.9 ± 0.4
-11	N/A	N/A	6.4 ± 0.4	9.7 ± 0.4	11.9 ± 1.0	13.2 ± 0.7
-14	N/A	N/A	6.8 ± 0.6	11.0 ± 0.9	16.4 ± 1.2	16.4 ± 0.9
-16	N/A	N/A	7.0 ± 0.6	9.7 ± 1.0	14.0 ± 1.4	15.5 ± 1.1

The header spans: "Distances (Å; ave±sdev)"

Supplementary Video 1 – Structural changes that occur during cold-induced unfolding of CylR2 at atomic resolution. Each frame shows a single structure taken from the ensembles of 20 lowest-energy NOE-based structures determined at 25 °C, -3 °C, -7 °C, -11 °C, -14 °C and -16 °C, respectively. For the majority of residues only back-bone heavy atoms are presented. For residues crucial for both tertiary and quaternary folding side chains are also shown.
