S1. Syntheses of compounds 2a and 2b

General Remarks

All manipulations were performed under an atmosphere of dry nitrogen using standard Schlenk techniques and in a dinitrogen filled glove box where the O₂ and H₂O levels were usually kept below 1 ppm. (Cy-cAAC)₂Si (**1a**) [cAAC = Cy-cAAC: = :C(CH₂)(CMe₂)(C₆H₁₀)N-2,6-*i*Pr₂C₆H₃] and (Me₂-cAAC)₂Si (**1b**) [cAAC = Me₂-cAAC: = :C(CH₂)(CMe₂)₂N-2,6-*i*Pr₂C₆H₃] were prepared according to the literature procedure. ^{S1} The crystals of silylones (**1a-b**) are stable in air for forty five minutes and after that they slowly loose their blue color. After twenty four hours they completely turn to colorless solid (mixture of cAAC=O, SiO₂ and (cAACH)₂Si(OH)₂) which is concluded from NMR resonances and MASS spectrometry.

Figure S1: Structures of precursors (Cy-cAAC)₂Si (1a) and (Me₂-cAAC)₂Si (1b).^{S1}

All solvents were dried initially with the M-Braun solvent drying system and then deoxygenated by stirring for 4-5 hours over Na/K alloy followed by distillation in vacuum and degassed. ¹H, ¹³C and ²⁹Si NMR spectra were recorded on Bruker Avance 500 MHz NMR spectrometer. Deuterated NMR solvent C₆D₆ was dried prior to use by stirring for 2 days over Na/K alloy followed by distillation in vacuum and degassed. EI-MS spectra were obtained with a Finnigan MAT 8230 or a Varian MAT CH5 instrument (70 eV) by EI-MS methods. Melting points were measured in sealed glass tubes on a Büchi B-540 melting point apparatus.

Important points about the reactivity of silylones (1a-b): Silylones were reacted with metal carbonyls, R_3B and other organic molecules like $R-N_3$ etc. The reactions did not produce exclusively one product rather a mixture of compounds and hence isolations and characterizations were restricted. To get control over these reactions is challenging due to the following reasons: 1) The HOMO is the π -bonded (three center-two-electron π -bond between two carbene carbon atoms and the central silicon atom) electron pair. 2) The π -back bonding (donation of electron from silicon to carbene carbon atoms) is higher than that of the σ -donation

from carbene carbon atoms to the central silicon atom. We realized that the conventional methods towards the activation of small organic molecules at silicon center of silylone are futile. Combined with previously reported theoretical calculations ^{S1} on silylones and several attempts for the activation of small organic molecules at central silicon atom led to the above mentioned conclusion. The unprecedented synthetic route (Figure S2) is thus very important.

Figure S2. Conversion of compounds 1a-b to 2a-b.

Synthesis of compound 2a: To a 1:1 molar mixture of compound **1a** (272 mg, 0.4 mmol) and metallic potassium (15 mg, 0.4 mmol), tetrahydrofuran (THF) (15 mL) was added at room temperature. The resulting dark purple solution was stirred along with the piece of metallic potassium for thirty five minutes to obtain a greenish-yellow solution. The solution was then filtered to separate the unreacted potassium (11 mg, 67 mol%) indicating that 33 mol% of K was consumed during the reaction. The THF solution was concentrated under vacuo to 0.5 mL to which 1 mL and stored at -32 °C in a freezer to form bright orange-yellow blocks of **2a** in 80% yield. The volume of the solvent plays a crucial role on the rate of conversion. On decreasing the volume of the solvent the reaction proceeds faster.

Compound 2a: Melting range 223-224 °C, UV-vis absorption band at $\lambda_{ab} = 423$ nm.

¹**H** NMR (500 MHz, 298 K, C₆D₆, ppm) δ : 7.19 (d, J = 7.5 Hz, 1H_{Ar}), 7.11-7.09 (m, 2.7, 3H_{Ar}), 6.89 (t, J = 7.6 Hz, 1H_{Ar}), 6.82 (d, J = 6.4 Hz, 1H_{Ar}), 4.57 (s, 1H, C_{carbene}-H), 3.77 – 3.69 (m, 1H, CHMe₂), 3.32 (dt, J = 13.3, 6.6 Hz, 1H, CHMe₂), 2.94 (dt, J = 13.7, 6.8 Hz, 1H, CHMe₂), 2.43 (d, J = 13.0 Hz, 1H, H_{cyclohexyl}), 2.33 – 2.19 (m, 4H, H_{cyclohexyl}), 2.16 – 2.02 (m, 3H; H_{cyclohexyl}), 1.96 – 1.79 (m, 4H), 1.77 – 1.64 (m, 7H), 1.51 – 1.40 (m, 12H, 2xNCMe₂), 1.28 (dd, J = 6.8, 2.4 Hz, 4H), 1.19 – 1.06 (m, 12H), 0.97 – 0.75 (m, 9H), 0.63 (d, J = 6.8 Hz, 2H, CH_{2cyclohexyl}), 0.46 (s, 2H, CH_{2cyclohexyl}).

¹³**C NMR** (126 MHz, 298 K, C₆D₆, ppm) δ : 173.50 (C_{cAAC}), 151.13, 148.72, 147.01, 146.05, 142.20, 139.61, 125.84, 125.17, 123.34, 122.29, 121.36, 69.47 (C_{cAAC} –H), 67.62, 63.76, 54.11, 52.95, 51.05, 46.07, 44.68, 41.37, 40.55, 39.78, 32.49, 31.91, 30.65, 28.76, 28.66, 28.29, 27.02, 26.90, 26.88, 26.78, 26.33, 26.22, 26.09, 25.30, 24.67, 24.44, 24.43, 23.75, 23.58, 23.42.

²⁹Si NMR (99 MHz, 298 K, C₆D₆, ppm) δ: 55.98.

EI-MS: m/z (%) 678.4 (100%)[M^+], 679.5 (63%)[M^+], 680.5 (23%)[M^+]. Mass spectrometry was performed on solid sample of **2a**.

Synthesis of compound 2b: To a 1:1 molar mixture of compound 1a (240 mg, 0.4 mmol) and metallic potassium (15 mg, 0.4 mmol), tetrahydrofuran (THF) (15 mL) was added at room temperature. The resulting dark purple solution was stirred along with the piece of metallic potassium for two hours to obtain a greenish-yellow solution. The solution was then filtered to separate the unreacted potassium (11 mg, 67 mol%) indicating that 33 mol% of K was consumed during the reaction. The THF solution was concentrated under vacuo to 0.5 mL to which 1 mL of *n*-hexane was added and the resulting solution was stored at -32 °C in a freezer to form bright orange-yellow blocks of 2b in 40% yield.

Point to be noted that in both the cases reaction solutions should not be stirred for longer than the time mentioned above since the products (2a-b) can undergo further rearrangements to produce a mixture of different products.

Compound 2b: Melting range 211-212 °C, UV-vis absorption band at $\lambda_{ab} = 420$ nm.

¹**H NMR** (500 MHz, 298 K, C₆D₆, ppm) δ : 7.11 – 7.07 (m, 4H), 6.88 (t, J = 7.6 Hz, 1H), 6.82 (dd, J = 7.7 Hz, 1.7, 1H), 4.29 (s, 1H, C_{cAAC}-H), 3.79 – 3.72 (m, 1H), 3.30 (dq, J = 13.5, 6.7 Hz, 1H), 2.92 (dt, J = 13.8, 6.9 Hz, 1H), 2.14 (d, J = 12.9 Hz, 1H), 1.84 (t, J = 8.8 Hz, 1H), 1.76 (s, 3H), 1.59 (d, J = 6.7 Hz, 3H), 1.46 (s, 3H), 1.45 – 1.38 (m, 19H), 1.37 (s, 3H), 1.16 (d, J = 6.8 Hz, 4H), 1.09 (d, J = 7.0 Hz, 6H), 0.76 (s, 3H), 0.63 (d, J = 6.9 Hz, 3H), 0.45 (s, 3H).

¹³**C NMR** (126 MHz, 298 K, C₆D₆, ppm) δ : 172.10 (C_{cAAC}), 151.17, 148.88, 148.43, 147.04, 142.60, 139.86, 125.97, 125.37, 123.53, 122.40, 121.57, 67.14, 66.25 (C_{cAAC} –H), 63.63, 60.79, 59.38, 47.86, 40.98, 35.93, 35.57, 34.42, 33.47, 32.26, 31.65, 30.76, 28.87, 28.84, 28.73, 27.75, 27.28, 27.13, 27.01, 26.90, 26.64, 26.08, 24.61, 23.95, 23.68.

²⁹Si NMR (99 MHz, 298 K, C₆D₆, ppm) δ: 54.55.

EI-MS: m/z (%): 598.4 (100%)[M⁺], 599.4 (63%)[M⁺], 600.4 (24%)[M⁺]. Mass spectrometry was performed on solid sample of **2b**.

Additional experiment: A similar reaction was performed following the synthesis of compound 2a in THF-d₈ and the NMR spectra confirmed the presence of C_{cAAC} –H resonance and no incorporation of the deuterium from THF-d₈ (confirmed by ¹³C NMR spectrum) was observed.

Scheme S1. Electronic structures of a) 1,2-singlet diradical (Cy-cAAC·)Si(·)Cl₂, b) 1,4-singlet diradical (Cy-cAAC·)₂Si₂Cl₄ c) silylene with three coordinate silicon 2a-b.

S2. Solid-state NMR characterization of compounds 1a and 2a

Solid-state NMR spectra of compound **1a** show a slight polymorphism with a chemical difference of the ²⁹Si resonance of 1.8 ppm in a stoichiometry of approximately 1.7:1. The chemical shift anisotropy of **1a** was obtained to be 125.8 and 129.3 ppm for the two peaks at 66.6 and 68.4, respectively, with an asymmetry of 0.52 in both cases (see Figure S4A). $^{1}H/^{29}Si$ cross polarization (CP) buildup curves show half-maximum intensity after approximately 1.2 ms (see Figure S3A).

Compound **2a** shows a single ²⁹Si resonance at 55.0 ppm. Fitting of spinning side bands resulted in a CSA of 58.0 ppm with an asymmetry of 0.7 (see Figure S4B). CP buildup (half-maximum intensity after 1.2 ms) occurs with similar time behaviour as for **1a** (see Figure S3B).

Figure S3: CP buildup curves for **1a** (A) and **2a** (B). Intensities are scaled to reflect relative values with respect to the maximal values obtained within the time course from 0 to 5.5 ms. In (A) the two resonances resulting from crystal polymorphism are displayed in red (66.8 ppm) and blue (68.6 ppm).

Figure S4: Chemical Shift Anisotropy determination as observed at 3 kHz MAS. (A) ²⁹Si spectrum of 1a. The data was fit to yield a CSA of 125.8 and 129.3 ppm for the two peaks at 66.6 and 68.4 ppm. (B) Spectrum of 2a at 3 kHz MAS, fit to yield a CSA of 58.0.

Experimental Details: Isotropic chemical shift spectra and cross polarization (CP) buildup was determined using 11 kHz MAS. For the buildup curves, 1024 scans were acquired over 1.5 h for each data point. Determination of chemical shift anisotropies (CSAs) from spinning side band patterns was pursued using a 5.5 ms CP contact time at 3 kHz MAS, using 10240 scans, recorded in 14 h for each of **1a** and **2a**. Spectral deconvolution and CSA fitting was done using Bruker Topspin software. All experiments were pursued at 600 MHz Larmor frequency in a 4 mm rotor at approximately 15 C. Direct acquisition times were set to 15 ms in the presence of 83 kHz Waltz-64 decoupling. Recycle delays were set to 5s. ¹H hard pulses were applied at 83 kHz and CP B₁ fields were set to approximately 50 kHz on ²⁹Si and 60 kHz on protons.

S3. UV-visible spectra of compounds 1a, 1b, 2a and 2b

UV-vis spectra were recorded on Varian Cary 5000 (Varian) spectrophotometer.

Figure S5. UV-vis spectra of compounds 1a-b (dotted line) and 2a-b (solid line) in *n*-hexane.

S4. Cyclic voltammogram of compounds 1a-b

Cyclic voltammograms of 1a

The cyclic voltammetry experiments have been performed at a Metrohm-Autolab potentiostat PGSTAT 101 in combination with Autolab NOVA 10.1.3. All experiments have been performed under argon atmosphere in deoxygenated and anhydrous 0.1 M [*n*-Bu₄N]PF₆ THF solution. The setup consisted of a glassy carbon (GC) working electrode (WE), a Pt wire as the counter electrode (CE) and a Ag wire as reference electrode (RE). The recorded voltammograms have been referenced to the internal standard $Cp_2^*Fe/Cp_2^*Fe^+$, which was added after the measurement.

Figure S6: Cyclic voltammogram of $(Cy-CAAC)_2Si$ (1a) in THF solution (0.1 M [*n*-Bu₄N]PF₆); a scan rate of 50 mVs¹ (CE: Pt, WE: GC, RE: Ag) scanned from -0.35 V to -2.85 V. The voltammogram shows three irreversible reductions and one quasi-reversible reduction (red curve).

Figure S7: Section cyclic voltammogram of (Cy-CAAC)₂Si (1a) in THF solution (0.1 M [*n*-Bu₄N]PF₆) at indicated scan rates (CE: Pt, WE: GC, RE: Ag).

Compounds **1a-b** were investigated by cyclic voltammetry in 0.1 M [*n*-Bu₄N]PF₆ THF solution (CE: Pt, WE: GC, RE: Ag). The voltammograms are referred against $\text{Cp}^*_2\text{Fe}/\text{Cp}^*_2\text{Fe}^+$ and show a quasi-reversible reduction at $E_{1/2} = 1.55$ V (**1a**) and 1.50 V (**1b**) which indicate the formation of radical anion (**1a-b**)⁻. In addition the measurements show three irreversible reductions (E = -1.07, -2.39 and -2.72 V for **1a**, see *Figure S6*).

Cyclic voltammogram of 1b

Figure S8: Section cyclic voltammogram of $(Me_2-CAAC)_2Si$ (1b) in THF solution (0.1 M [*n*-Bu₄N]PF₆) at 50 mVs⁻ scan rates (CE: Pt, WE: GC, RE: Ag); $E_{1/2} = 1.50$ V.

S6. EPR spectroscopy

Continuous-wave (CW) EPR spectra were recorded at X-band microwave frequencies (9 GHz) using a Bruker ElexSys E500 spectrometer with a Bruker SuperX CW bridge. The spectrometer was equipped with the Bruker SHQ rectangular microwave cavity (Bruker 4122SHQ) and a helium flow cryostat (Oxford Instruments) for low temperature experiments. $(cAAC)_2Si$ (1a-b) has diamagnetic singlet spin ground state (S = 0). (Me₂-CAAC)₂Si (1b) was reacted with potassium for thirty minutes to *in situ* generated radical anion (Me₂-CAAC)₂Si · (1b·⁻). The EPR spectrum of the resultant solution was recorded.

Figure S9. X-band EPR spectrum (left) of THF solution of $(Me_2-CAAC)_2Si^{-1}$ (**1b**⁻¹) at 298 K ($v_{\mu W} = 9.418$ GHz, $B_{mod} = 0.5$ G at 100 kHz). The g = 2.0058, α (^{15}N ; I = 1) = 5.89 G and α (^{13}C ; I = 1/2) = 40 G (left). The structure of radical anion (Me₂-CAAC)₂Si (**1b**⁻¹) (right).

EPR spectrum of $(Me_2-CAAC)_2Si$ (1b⁻) suggests that the radical electron is delocalized between two carbon atoms and one silicon atom. The hyperfine lines originate due to the coupling of a radical electron with two nitrogen nuclei (¹⁵N; *I* = 1).

S6. Crystal data of 2a and 2b

All experiments were performed on Bruker SMART APEX II systems based on D8 three-circle goniometers with Incoatec microfocus X-ray sources (IµS) and Incoatec QUAZAR mirror optics.^{S2} Suitable single crystals of **2a** and **2b** were mounted at low temperature in inert oil under argon atmosphere by applying the X–Temp2 device. ^{S3-4} The data were collected at 100 K crystal temperature (Mo source: Bruker CRYOFLEX; Ag source Oxford Cryosystems CRYOSTREAM 700), 50 kV and 600 µA for both machines and an appropriate 0.5° omega scan strategy for the wavelength in question. Data reduction was performed with SAINT v7.68A^{S5} out of the APEX II v2.2012.2 0 program package. ^{S6} SADABS (version 2014/4) was employed for the incident beam scaling, determination of the spherical harmonic coefficients, outlier rejection and determination of the error model parameters. All the structures were solved by direct methods with SHELXS.^{S7} They were refined by full-matrix least-squares against F² using SHELXL-2014/3 with the help of the SHELXIe graphical user interface.^{S8} All non-hydrogen atoms were refined with anisotropic displacement parameters. The hydrogen atoms, except H(1), were set to idealized positions and refined using a riding model with their isotropic displacement parameters constrained to be 1.5 times the equivalent isotropic displacements of the atoms to which they

were attached for methyl hydrogens and 1.2 times for all other hydrogens. The coordinates of H(1) were freely refined.

The following ALERTS were generated. Each ALERT has the format test-name_ALERT_alert-type_alert-level.

Click on the hyperlinks for more details of the test.

Alert level G

```
PLAT793 ALERT 4 GThe Model has Chirality at C1SVerifyPLAT912 ALERT 4 GMissing # of FCF Reflections Above STh/L=0.60041Note
```

0 ALERT level A = Most likely a serious problem - resolve or explain 0 ALERT level B = A potentially serious problem, consider carefully 0 ALERT level C = Check. Ensure it is not caused by an omission or oversight 2 ALERT level G = General information/check it is not something unexpected 0 ALERT type 1 CIF construction/syntax error, inconsistent or missing data 0 ALERT type 2 Indicator that the structure model may be wrong or deficient

0 ALERT type 3 Indicator that the structure quality may be low

2 ALERT type 4 Improvement, methodology, query or suggestion 0 ALERT type 5 Informative message, check

S7. Theoretical calculation on 2a

Computational Details:

All calculations were performed in Gaussian09 quantum package.^{S9} All intermediates are optimized with the global-hybrid meta-GGA to DFT functional, U/R-M06-2X^{S10} with SVP^{S11} basis sets for all atoms. Geometry optimization of 2a also carried out using CASSCF(2,2) ^{S12} level with SVP basis sets. Geometry was fully optimized without symmetry constraints. Harmonic force constants were computed at the optimized geometry to confirm if the optimized geometry is located at minima or saddle point on the potential energy surface. For further validation of the energy change, we have also performed single point calculation of optimized geometry incorporating higher basis set TZVP^{S13} for all atoms. Solvation energies in THF (ϵ = 7.426) were evaluated by a self-consistent reaction field (SCRF) approach using the SMD continuum solvation model.^{S14} NBO analysis and Mulliken spin density calculations were performed at U/R-M06-2X/TZVP//U/R-M06-2X/SVP level. All the energy values reported in the manuscript are at U/R-M06-2X/TZVP//U/R-M06-2X/SVP level. The wavefunction file generated from the quantum code was used to perform QTAIM^{S15} analysis in the AIMALL program suite. We have applied Bader's AIM (Atoms-in-molecule)^{S16} concept to characterize the electron distribution in 2a. Any bonded pair of atoms has a bond path, *i.e.*; a connecting line with maximum electron density. The bond critical point (BCP) is a point on this line where the gradient $\nabla \rho(\mathbf{r})$ of the density is equal to zero. The magnitude of the electron density, $\rho(\mathbf{r})$ and its Laplacian, $\nabla^2 \rho(\mathbf{r})$ at the BCP provide information about the strength and type of bond. The Laplacian indicates whether the density is locally concentrated ($\nabla^2 \rho < 0$) or depleted ($\nabla^2 \rho > 0$). Optimized geometries and orbital diagrams are rendered in the Chemcraft visualization software.^{S17}

Closed-shell singlet

Diradical singlet

Figure S12: Superposition of crystal structure of **2a** with optimized geometries of different spin states at U/R-M06-2X/SVP level (top). Calculated energy values (bottom) of the a) singlet (**2a**), b) singlet 1,2-diradical (**2a**') and c) triplet 1,2 diradical (**2a**'') species implying the preference for singlet ground state (**2a**) (bottom).

Table S3. Calculated geometrical parameters in closed-shell singlet, triplet and diradical singlet

 electronic states of compound 2a.

Table S4. BCP parameters for 2a

| Atoms | $\rho(\mathbf{r})$, a.u. | $\nabla^2 \rho(\mathbf{r})$, a.u. | 3 | DI |
|---------|---------------------------|------------------------------------|-------|------|
| Si1-C24 | +0.12 | +0.42 | +0.51 | 0.99 |
| Si1-C23 | +0.10 | +0.16 | +0.13 | 0.58 |
| Si1-C1 | +0.10 | +0.19 | +0.15 | 0.56 |
| C24-N2 | +0.30 | -0.77 | +0.06 | 1.16 |

Figure S13. Contour plot of Laplacian distribution $[\nabla^2 \rho(\mathbf{r})]$ in the Si1-C24-N2 plane of **2a**. For other conventions refer Figure 1. Solid lines indicate the areas of charge concentration ($\nabla^2 \rho(\mathbf{r}) < 0$) while dotted lines mean the charge depletion ($\nabla^2 \rho(\mathbf{r}) > 0$). The range of contours of the Laplacian is -8×10^2 to $+8 \times 10^2$. Solid lines connecting atomic nuclei (black) are the bond paths and those lines (purple) separating the atomic basins indicates the zero-flux surface crossing the molecular plane.

Figure S14. KS-MO of some intermediates (isosurface = 0.006 au). Hydrogen atoms are omitted for clarity.

Table S5. The energy changes (in kcal/mol) for all steps involved in the transformation $1a \rightarrow 2a$. The term ΔE_e and ΔG_{298} are electronic energy and Gibbs free energy change at M06-2X/SVP level, ΔG_L^S is the Gibbs free energy change in solvent at M06-2X/TZVP//M06-2X/SVP level.

| Steps | ΔE _e | ΔG_{298} | ΔG_{L}^{S} |
|-----------------------------|-----------------|------------------|--------------------|
| $1a \rightarrow (1a)^{-1}$ | -8.7 | -12.0 | -13.2 |
| $(1a)^{-} \rightarrow IM_1$ | 17.4 | 16.4 | 17.9 |
| $IM_1 \rightarrow IM_2$ | -24.7 | -22.6 | -23.3 |
| $IM_2 \rightarrow 2a$ | -7.6 | -4.8 | -2.6 |

Scheme S². Energy change (ΔG_L^s at U/R-M06-2X/TZVP//U/R-M06-2X/SVP level) of hydrogen transfer step for model systems.

S8. Mass spectra of compounds 1a, 1b, 2a and 2b:

Mass spectra of compound 1a

EI-MS: m/z (%) 678.5 (100%)[M⁺], 679.5 (58%)[M⁺], 680.5 (20%)[M⁺]. Mass spectrometry was performed on solid sample of 1a.

Mass spectra of compound 1b

EI-MS: m/z (%) 598.47 (100%)[M^+], 599.47 (58%)[M^+], 600.47 (20%)[M^+]. Mass spectrometry was performed on solid sample of **1b**.

Mass spectra of compound 2a

Mass spectra of compound 2b

S9. Geometry of the atoms in 2a

One carbene carbon atom (C24) adopts a nearly ideal trigonal planar geometry with a sum of angles of 358.4° which is close to those of mono radical $(357.33^{\circ})^{S22}$ and diradical (Cy-cAAC·)₂SiCl₂ (354.8°, 355.7°),^{S23} while the corresponding sum of angles of proton containing carbene carbon atom (C1) is 336.5°. The latter value is wider by 6° when compared with that of (Me₂-cAAC-H)₂O (330.26°).^{S24}
