# The Mondshein Sequence 

Jens M. Schmidt<br>Max Planck Institute for Informatics

#### Abstract

Canonical orderings [STOC'88, FOCS'92] have been used as a key tool in graph drawing, graph encoding and visibility representations for the last decades. We study a far-reaching generalization of canonical orderings to non-planar graphs that was published by Lee Mondshein in a PhD-thesis at M.I.T. as early as 1971.

Mondshein proposed to order the vertices of a graph in a sequence such that, for any $i$, the vertices from 1 to $i$ induce essentially a 2 -connected graph while the remaining vertices from $i+1$ to $n$ induce a connected graph. Mondshein's sequence generalizes canonical orderings and became later and independently known under the name non-separating ear decomposition. Currently, the best known algorithm for computing this sequence achieves a running time of $O(n m)$; the main open problem in Mondshein's and follow-up work is to improve this running time to a subquadratic time.

In this paper, we present the first algorithm that computes a Mondshein sequence in time and space $O(m)$, improving the previous best running time by a factor of $n$. In addition, we illustrate the impact of this result by deducing linear-time algorithms for several other problems, for which the previous best running times have been quadratic.

In particular, we show how to compute three independent spanning trees in a 3 -connected graph in linear time, improving a result of Cheriyan and Maheshwari [J. Algorithms 9(4)]. Secondly, we improve the preprocessing time for the output-sensitive data structure by Di Battista, Tamassia and Vismara [Algorithmica 23(4)] that reports three internally disjoint paths between any given vertex pair from $O\left(n^{2}\right)$ to $O(m)$. Finally, we show how a very simple linear-time planarity test can be derived once a Mondshein sequence is computed.

keywords: Mondshein sequence, graph drawing, canonical ordering, non-separating ear decomposition, independent spanning trees, reporting disjoint paths

## 1 Introduction

Canonical orderings are a fundamental tool used in graph drawing, graph encoding and visibility representations; we refer to [1] for a wealth of applications. For maximal planar graphs, canonical orderings were first introduced by de Fraysseix, Pach and Pollack [6, 7] in 1988. Kant then generalized canonical orderings to arbitrary 3 -connected planar graphs [12, 13].

Surprisingly, the concept of canonical orderings can be traced back much further, namely to a long-forgotten PhD-thesis at M.I.T. by Lee F. Mondshein [15] in 1971. In fact, Mondshein proposed a sequence that generalizes canonical orderings to non-planar graphs, hence making them applicable to arbitrary 3 -connected graphs. Mondshein's sequence was, independently and in a different notation, found later by Cheriyan and Maheshwari [4] under the name non-separating ear decompositions.

Computationally, it is an intriguing question how fast a Mondshein sequence can be computed. Mondshein himself gave an involved algorithm with running time $O\left(m^{2}\right)$. Cheriyan showed that
it is possible to achieve a running time of $O(n m)$ by using a theorem of Tutte that proves the existence of non-separating cycles in 3 -connected graphs [19]. Both works (see [15, p 1.2] and [4, p. 532]) state as main open problem, whether it is possible to compute a Mondshein sequence in subquadratic time.

We present the first algorithm that computes a Mondshein sequence in time and space $O(m)$, hence solving the above 40 -year-old problem. The interest in such a computational result stems from the fact that 3 -connected graphs play a crucial role in algorithmic graph theory; we illustrate this in three direct applications by giving linear-time (and hence optimal) algorithms for several problems, for two of which the previous best running times have been quadratic.

In particular, we show how to compute three independent spanning trees in a 3 -connected graph in linear time, improving a result of Cheriyan and Maheshwari [4]. Second, we improve the preprocessing time from $O\left(n^{2}\right)$ to $O(m)$ for a data structure by Di Battista, Tamassia and Vismara [8] that reports three internally disjoint paths in a 3 -connected graph between any given vertex pair in time $O(\ell)$, where $\ell$ is the total length of these paths. Finally, we illustrate the usefulness of Mondshein's sequence by giving a very simple linear-time planarity test, once a Mondshein sequence is computed.

We start by giving an overview of Mondshein's work and its connection to canonical orderings and non-separating ear decompositions in Section 3. Section 4 explains the idea of our linear-time algorithm and states its main technical lemma, the Path Replacement Lemma. An in-depth proof of correctness of this lemma is then given in Section 5. Section 6 covers three applications of our linear-time algorithm.

## 2 Preliminaries

We use standard graph-theoretic terminology and assume that all graphs are simple.
Definition 1 ([14, 21]). An ear decomposition of a 2-connected graph $G=(V, E)$ is a sequence $\left(P_{0}, P_{1}, \ldots, P_{k}\right)$ of subgraphs of $G$ that partition $E$ such that $P_{0}$ is a cycle and every $P_{i}, 1 \leq i \leq k$, is a path that intersects $P_{0} \cup \cdots \cup P_{i-1}$ in exactly its end points. Each $P_{i}$ is called an ear. An ear is short if it is an edge and long otherwise.

According to Whitney [21], every ear decomposition has exactly $m-n+1$ ears. For any $i$, let $G_{i}=P_{0} \cup \cdots \cup P_{i}$ and $\overline{V_{i}}:=V-V\left(G_{i}\right)$. We write $\overline{G_{i}}$ to denote the graph induced by $\overline{V_{i}}$. We observe that $\overline{G_{i}}$ does not necessarily contain all edges in $E-E\left(G_{i}\right)$; in particular, there may be short ears in $E-E\left(G_{i}\right)$ that have both of their endpoints in $G_{i}$.

For a path $P$ and two vertices $x$ and $y$ in $P$, let $P[x, y]$ be the subpath in $P$ from $x$ to $y$. A path with endpoints $v$ and $w$ is called a $v w$-path. A vertex $x$ in a $v w$-path $P$ is an inner vertex of $P$ if $x \notin\{v, w\}$. For convenience, every vertex in a cycle is an inner vertex of that cycle.

The set of inner vertices of an ear $P$ is denoted as inner $(P)$. The inner vertex sets of the ears in an ear decomposition of $G$ play a special role, as they partition $V(G)$. Every vertex of $G$ is contained in exactly one long ear as inner vertex. This gives readily the following characterization of $\overline{V_{i}}$.

Observation 2. For every $i, \overline{V_{i}}$ is the union of the inner vertices of all long ears $P_{j}$ with $j>i$.
We will compare vertices and edges of $G$ by their first occurrence in a fixed ear decomposition.
Definition 3. Let $D=\left(P_{0}, P_{1}, \ldots, P_{m-n}\right)$ be an ear decomposition of $G$. For an edge $e \in G$, let $\operatorname{birth}_{D}(e)$ be the index $i$ such that $P_{i}$ contains $e$. For a vertex $v \in G$, let $\operatorname{birth} h_{D}(v)$ be the minimal
$i$ such that $P_{i}$ contains $v$ (thus, $P_{b i r t h_{D}(v)}$ is the ear containing $v$ as an inner vertex). Whenever $D$ is clear from the context, we will omit $D$.

Clearly, for every vertex $v$, the ear $P_{\text {birth }(v)}$ is long, as it contains $v$ as an inner vertex.

## 3 Generalizing Canonical Orderings

We give a compact rephrasing of canonical orderings in terms of non-separating ear decompositions. This will allow for an easier comparison of a canonical ordering and its generalization to non-planar graphs, as the latter is also based on ear decompositions. We assume that the input graphs are 3 -connected and, when talking about canonical orderings, planar. It is well-known that maximal planar graphs, which were considered in [6], form a subclass of 3 -connected graphs (apart from the triangle-graph).

Definition 4. An ear decomposition is non-separating if, for $0 \leq i \leq m-n$, every inner vertex of $P_{i}$ has a neighbor in $\overline{G_{i}}$ unless $\overline{G_{i}}=\emptyset$.

The name non-separating refers to the following helpful property.
Lemma 5. In a non-separating ear decomposition $D, \overline{G_{i}}$ is connected for every $i$.
Proof. Let $u$ be an inner vertex of the last long ear in $D$. If $\overline{G_{i}}=\emptyset$, the claim is true. Otherwise, consider any vertex $x$ in $\overline{G_{i}}$. In order to show connectedness, we exhibit a path from $x$ to $u$ in $\overline{G_{i}}$. If $x$ is an inner vertex of $P_{\text {birth }(u)}$, this path is just the path $P_{\text {birth }(u)}[x, u]$. Otherwise, $\operatorname{birth}(x)<\operatorname{birth}(u)$. Then $x$ has a neighbor in $\overline{G_{b i r t h(x)}}$, since $D$ is non-separating, and, according to Observation 2, this neighbor is an inner vertex of some ear $P_{j}$ with $j>\operatorname{birth}(x)$. Applying induction on $j$ gives the desired path to $u$.

A plane graph is a graph that is embedded into the plane. In particular, a plane graph has a fixed outer face. We define canonical orderings as special non-separating ear decompositions.

Definition 6 (canonical ordering). Let $G$ be a 3-connected plane graph having the edges $t r$ and $r u$ in its outer face. A canonical ordering with respect to $t r$ and $r u$ is an ear decomposition $D$ of $G$ such that

1. $t r \in P_{0}$,
2. $P_{\text {birth }(u)}$ is the last long ear, contains $u$ as its only inner vertex and does not contain $r u$, and
3. $D$ is non-separating.

The fact that $D$ is non-separating plays a key role for both canonical orderings and their generalization to non-planar graphs. E.g., for canonical orderings, Lemma 5 implies that the plane graph $G$ can be constructed from $P_{0}$ by successively inserting the ears of $D$ to only one dedicated face of the current embedding, a routine that is heavily applied in graph drawing and embedding problems.

The original definition of canonical orderings by Kant [13] states the following additional properties.

Lemma 7 (further properties). For every $0 \leq i \leq m-n$ in a canonical ordering,
4. the outer face $C_{i}$ of the plane subgraph $G_{i} \subseteq G$ is a (simple) cycle that containstr,
5. $G_{i}$ is 2 -connected and every separation pair of $G_{i}$ has both its vertices in $C_{i}$,
6. for $i>0$, the neighbors of inner $\left(P_{i}\right)$ in $G_{i-1}$ are contained consecutively in $C_{i-1}$, and
7. if $\mid$ inner $\left(P_{i}\right) \mid \geq 2$, each inner vertex of $P_{i}$ has degree two in $G_{i}$.

Properties 4 and 5 can be easily deduced from Definition 6 as follows: Every $G_{i}$ is a 2-connected plane subgraph of $G$, as $G_{i}$ has an ear decomposition. According to [18, Corollary 1.3], all faces of a 2 -connected plane graph form cycles. Thus, every $C_{i}$ is a cycle and Property 4 follows directly from the fact that $t r$ is assumed to be in the fixed outer face of $G$. As noted in [1, Lemma 1], the 3-connectivity of $G$ implies Property 5. Property 6 follows from Property 4, the fact that every inner vertex of $P_{i}$ must be outside $C_{i-1}$ (in $G$ ) and the Jordan Curve Theorem.

For the sake of completeness, we show how Property 7 is derived. Although it is not directly implied by Definition 6, the following lemma shows that we can always assume it.

Lemma 8. Every canonical ordering can be transformed to a canonical ordering satisfying Property 7 in linear time.
Proof. Consider any ear $P_{i} \neq P_{0}$ with $\left|\operatorname{inner}\left(P_{i}\right)\right| \geq 2$ such that an inner vertex $x$ of $P_{i}$ has a neighbor $y$ in $G_{i-1}$. Then $P_{\operatorname{birth}(x y)}=x y$ and $\operatorname{birth}(x y)>i$. Let $Z_{1}$ be a shortest path in $P_{i}$ from an endpoint of $P_{i}$ to $x$ and let $Z_{2}$ be the path in $P_{i}$ from $x$ to the remaining endpoint. Replace $P_{i}$ with the two ears $Z_{1} \cup x y$ and $Z_{2}$ and delete $P_{\operatorname{birth}(x y)}$. This preserves Properties 1-3 (note that $u \notin P_{i}$, as $\mid$ inner $\left(P_{i}\right) \mid \geq 2$ ).

If a vertex $x \in\{r, t\}$ has not degree 2 in $P_{0}$, it has a non-consecutive neighbor $y$ in $P_{0}$. We replace $P_{0}$ with the shortest cycle $C$ in $P_{0} \cup x y$ that contains $r, t$ and $y$, delete $P_{\text {birth }(x y)}=x y$ and add the remaining path from $x$ to $y$ in $P_{0}-E(C)$ as new ear directly after $C$. This clearly preserves Properties 1-3. We shortcut $P_{0}$ in a similar way, when $r$ and $t$ have degree 2 in $P_{0}$ and some vertex $x \in P_{0}-r-t$ has not degree 2. It is easy to see that the above operations can be computed in linear total time.

Our definition of canonical orderings uses planarity only in one place: $t r \cup r u$ is assumed to be part of the outer face of $G$. Note that the essential art of this assumption is that $\operatorname{tr} \cup r u$ is part of some face of $G$, as we can always choose an embedding for $G$ having this face as outer face. By dropping this assumption, our definition of canonical orderings can be readily generalized to non-planar graphs: We merely require $t r$ and $r u$ to be edges in the graph.

This is in fact equivalent to the definition Mondshein used 1971 to define a (2,1)-sequence [15, Def. 2.2.1], but which he gave in the notation of a special vertex ordering. This vertex ordering actually refines the partial order inner $\left(P_{0}\right), \ldots, \operatorname{inner}\left(P_{m-n}\right)$ by enforcing an order on the inner vertices of each path according to their occurrence on that path (in any direction). For conciseness, we will instead stick to the following short ear-based definition, which is similar to the one given in [4] but does not need additional degree-constraints.

Definition 9 ([15, 4]). Let $G$ be a graph with an edge ru. A Mondshein sequence avoiding ru (see Figure 1) is an ear decomposition $D$ of $G$ such that

1. $r \in P_{0}$,
2. $P_{b i r t h(u)}$ is the last long ear, contains $u$ as its only inner vertex and does not contain $r u$, and
3. $D$ is non-separating.

An ear decomposition $D$ that satisfies Conditions 1 and 2 is said to avoid ru. Put simply, this forces $r u$ to be "added last" in $D$, i.e., strictly after the last long ear $P_{\text {birth }(u)}$ has been added. Note that Definition 9 implies $u \notin P_{0}$, as $P_{\text {birth }(u)}$ contains only one inner vertex. As a direct consequence of this and the fact that $D$ is non-separating, $G$ must have minimum degree 3 in order to have a Mondshein sequence. Mondshein proved that every 3 -connected graph has a Mondshein sequence. In fact, also the converse is true.

Theorem 10. [4, 22] Let $r u \in E(G)$. Then $G$ is 3-connected if and only if $G$ has a Mondshein sequence avoiding ru.

Figure 1: A Mondshein sequence of a non-planar 3-connected graph.

We state two additional facts about Mondshein sequences. Since we replaced the assumption that $t r \cup r u$ is in the outer face of $G$ with the very small assumption that $r u$ is an edge of $G$ (which does not assume anything about $t$ at all), it is natural to ask how we can extract $t$ (and thus, a canonical ordering) from a Mondshein sequence when $G$ is plane. We choose $t$ as any neighbor of $r$ in $P_{0}$. Since $P_{0}$ is non-separating and the non-separating cycles of a 3-connected plane graph are precisely its faces [19], this satisfies Definition 6 and leads to the following observation.

Observation 11. Let $D$ be a Mondshein sequence avoiding ru of a planar graph $G$ and let $t$ be a neighbor of $r$ in $P_{0}$. Then $D$ is a canonical ordering of the planar embedding of $G$ whose outer face contains $t r \cup r u$.

Once having a Mondshein sequence, we can aim for a slightly stronger structure. A chord of an ear $P_{i}$ is an edge in $G$ that joins two non-adjacent vertices of $P_{i}$. Let a Mondshein sequence be induced if $P_{0}$ is induced in $G$ and every ear $P_{i} \neq P_{0}$ has no chord in $G$, except possibly the chord joining the endpoints of $P_{i}$. The following lemma shows that we can always expect Mondshein sequences that are induced.

Lemma 12. Every Mondshein sequence can be transformed to an induced Mondshein sequence in linear time.

Proof. Consider any ear $P_{i} \neq P_{0}$ that has a chord $x y$ such that the endpoints of $P_{i}$ are not $\{x, y\}$. Let $Z$ be the path obtained from $P_{i}$ by replacing $P_{i}[x, y] \subseteq P_{i}$ with $x y$; we call the latter operation short-cutting. We replace $P_{i}$ with the two ears $Z$ and $P_{i}[x, y]$ in that order and delete $P_{\text {birth }(x y)}=x y$. Clearly, this preserves the sequence to be a Mondshein sequence.

In order to make $P_{0}$ induced, consider the subgraph $H$ of $G$ that consists of $P_{0}$ and the chords of $P_{0}$. Let $t$ be a neighbor of $r$ in $P_{0}$ and let $C$ be a shortest cycle in $H$ that contains $r$ and $t$. We replace $P_{0}$ with $C$ and replace every ear $P_{i}$ that is a chord of $P_{0}$ and contained in $C$ with the path in $P_{0}$ that has been short-cutted by $P_{i}$, followed by moving that path to the position directly after $P_{0}$. This preserves the sequence to be a Mondshein sequence. It is easy to see that the above operations can be computed in linear total time.

## 4 Computing a Mondshein Sequence

Mondshein gave an involved algorithm [15] that computes his sequence in time $O\left(m^{2}\right)$. Independently, Cheriyan and Maheshwari gave an algorithm that runs in time $O(n m)$ and which is based on a theorem of Tutte. At the heart of our linear-time algorithm is the following classical construction of 3-connected graphs due to Barnette and Grünbaum [2] and Tutte [20, Thms. 12.64 and 12.65].

Definition 13. The following operations on simple graphs are $B G$-operations (see Figure 2).
(a) vertex-vertex-addition: Add an edge between two distinct non-adjacent vertices
(b) edge-vertex-addition: Subdivide an edge $a b, a \neq b$, by a vertex $v$ and add the edge $v w$ for a vertex $w \notin\{a, b\}$
(c) edge-edge-addition: Subdivide two distinct edges by vertices $v$ and $w$, respectively, and add the edge $v w$

Figure 2: BG-operations

Theorem 14 ([2, 20]). A graph is 3-connected if and only if it can be constructed from $K_{4}$ using $B G$-operations.

Hence, applying an BG-operation on a 3-connected graphs preserves it to be simple and 3connected. Let a $B G$-sequence of a 3 -connected graph $G$ be a sequence of BG-operations that constructs $G$ from $K_{4}$. It has been shown that such a BG-sequence can be computed efficiently.

Theorem 15 ([17, Thms. 6.(2) and 52]). A BG-sequence of a 3-connected graph can be computed in time $O(m)$.

The outline of our algorithm is as follows. We start with a Mondshein sequence of $K_{4}$, which is easily obtained, and compute a BG-sequence of our 3-connected input graph by using Theorem 15. The crucial part is now a careful analysis that a Mondshein sequence of a 3-connected graph $G$ can be modified to one of $G^{\prime}$, where $G^{\prime}$ is obtained from $G$ by applying a BG-operation.

This last step is the main technical contribution of this paper and depends on the various positions in the sequence in which the vertices and edges that are involved in the BG-operation can occur. We will prove that there is always a modification that is local in the sense that the only long ears that are modified are the ones containing a vertex that is involved in the BG-operation.

Lemma 16 (Path Replacement Lemma). Let $G$ be a 3-connected graph with an edge ru. Let $D=\left(P_{0}, P_{1}, \ldots, P_{m-n}\right)$ be a Mondshein sequence avoiding ru of $G$. Let $G^{\prime}$ be obtained from $G$ by applying a single $B G$-operation $\Gamma$ and let $r u^{\prime}$ be the edge of $G^{\prime}$ corresponding to ru. Then a Mondshein sequence $D^{\prime}$ of $G^{\prime}$ avoiding ru' can be computed from $D$ using only constantly many constant-time modifications.

We need some notation for describing the modifications. Let $v w$ be the edge that was added by $\Gamma$ such that, if applicable, $v$ subdivides $a b \in E(G)$ and $w$ subdivides $c d \in E(G)$. Then the edge $r u^{\prime}$ of $G^{\prime}$ that corresponds to $r u$ in $G$ is either $r u, r v$ or $r w$. Whenever we consider the edge $a b$ or $c d$, e.g. in a statement about $\operatorname{birth}(a b)$, we assume that $\Gamma$ subdivides $a b$, respectively, $c d$. W.l.o.g., we further assume that $\operatorname{birth}(a) \leq \operatorname{birth}(b), \operatorname{birth}(c) \leq \operatorname{birth}(d)$ and $\operatorname{birth}(d) \leq \operatorname{birth}(b)$. If not stated otherwise, the birth-operator refers always to $D$ in this section. Let $S \subseteq\{a v, v b, v w, c w, w d\}$ be the set of new edges in $G^{\prime}$.

We prove the Path Replacement Lemma by giving a detailed replacement scheme as follows.

Lemma 17. There is a Mondshein sequence $D^{\prime}=\left(P_{0}^{\prime}, P_{1}^{\prime}, \ldots, P_{m-n+1}^{\prime}\right)$ of $G^{\prime}$ avoiding ru (respectively, rv or rw if $\Gamma$ subdivides ru) that can be obtained from $D$ by performing the following four modifications:
M1) replacing the long ear $P_{\text {birth(b) }}$ with $1 \leq i \leq 3$ consecutive long ears $P_{b_{1}}^{\prime}, P_{b_{2}}^{\prime}$ and $P_{b_{3}}^{\prime}$, each of which consists of edges in $P_{\text {birth(b) }} \cup S$ (for notational convenience, we assume that all three ears exist such that $P_{b_{j}}^{\prime}:=P_{b_{i}}^{\prime}$ for every $j>i$ )
M2) if $P_{\text {birth }(c d)}$ is long and birth $(d)<b i r t h(b)$, replacing $P_{b i r t h(c d)}$ with the long ear $P_{\text {cwd }}^{\prime}$ that is obtained from $P_{\text {birth }(c d)}$ by subdividing $c d$ with $w$ (in particular, $\operatorname{birth}(c d)=\operatorname{birth}(d)<\operatorname{birth}(b)$ in this case)
M3) if $P_{\text {birth (ab) }}$ is short, deleting or replacing $P_{\text {birth(ab) }}$ with an edge in $\{v a, v b, v w\}$; if $P_{\text {birth(cd) }}$ is short, deleting or replacing $P_{\text {birth }(c d)}$ with an edge in $\{w c, w d\}$
M4) possibly adding $v w$ as new last ear
In particular, $D^{\prime}$ can be constructed from $D$ as follows (Figures 3 and 4 determine the new ears $P_{b_{1}}^{\prime}-P_{b_{3}}^{\prime}$ of $M 1$ ).
(1) $\Gamma$ is a vertex-vertex-addition

Obtain $D^{\prime}$ from $D$ by adding the new ear $v w$ at the end.
(2) $\Gamma$ is an edge-vertex-addition
(a) $\operatorname{birth}(b)=\operatorname{birth}(a b)$

Let $a^{\prime}$ and $b^{\prime}$ be the endpoints of $P_{\text {birth(b) }}$ such that $a^{\prime}$ is closer to $a$ than to $b$ on $P_{\text {birth(b) }}$ ( $a^{\prime}$ may be $a$, but $b^{\prime} \neq b$ ).
(i) $w \notin G_{b i r t h(b)}$
$\triangleright \operatorname{birth}(w)>\operatorname{birth}(b)$
Obtain $D^{\prime}$ from $D$ by subdividing $a b \subseteq P_{\text {birth }(b)}$ with $v$ and adding the new ear $v w$ at the end.
(ii) $w \in G_{b i r t h(b)}-P_{\text {birth }(b)} \quad \triangleright \operatorname{birth}(w)<\operatorname{birth}(b)$ and $w \notin\left\{a^{\prime}, b^{\prime}\right\}$ Let $Z$ be the path obtained from $P_{\text {birth(b) }}$ by replacing $a b$ with $a v \cup v b$. Let $Z_{1}$ be the $a^{\prime} w$-path in $Z \cup v w$. Obtain $D^{\prime}$ from $D$ by replacing $P_{\text {birth(b) }}$ with the two ears $Z_{1}$ and $Z\left[v, b^{\prime}\right]$ in that order.
(iii) $w \in P_{\text {birth }(b)} \quad \triangleright \operatorname{birth}(w)=\operatorname{birth}(b)$ or $w \in\left\{a^{\prime}, b^{\prime}\right\}$

Let $Z$ be obtained from $P_{\text {birth(b) }}$ by replacing $a b$ with $a v \cup v b$. Let $Z_{2}$ be the $v w$-path in $Z$ (if $\operatorname{birth}(b)=0, Z$ is a cycle and there are two $v w$-paths; we then choose one that does not contain $r$ as an inner vertex). Let $Z_{1}$ be obtained from $Z$ by replacing $Z_{2}$ with the edge $v w$. Obtain $D^{\prime}$ from $D$ by replacing $P_{\text {birth(b) }}$ with the two ears $Z_{1}$ and $Z_{2}$ in that order.
(b) $\operatorname{birth}(b)<\operatorname{birth}(a b)$ and $P_{\text {birth }(a b)}=a b$
(i) $\operatorname{birth}(w)>\operatorname{birth}(b)$
$\triangleright w \notin G_{b i r t h(b)}$
Obtain $D^{\prime}$ from $D$ by deleting $P_{\text {birth }(a b)}=a b$, adding the new ear $a v \cup v b$ directly after $P_{\text {birth(b) }}$ and adding the new ear $v w$ at the end.
(ii) $\operatorname{birth}(w)<\operatorname{birth}(b) \quad \triangleright w \in G_{b i r t h(b)-1}$ and $\operatorname{birth}(b)>0$ (A) $\operatorname{birth}(a)<\operatorname{birth}(b)$ and $a b=r u$

Obtain $D^{\prime}$ from $D$ by adding the new ear $w v \cup v b$ directly after $P_{\text {birth(b) }}$ and replacing $P_{b i r t h(a b)}=a b$ with $a v$.
(B) $\operatorname{birth}(a)<\operatorname{birth}(b)$ and $a b \neq r u$

Obtain $D^{\prime}$ from $D$ by adding the new ear $a v \cup v w$ directly after $P_{\text {birth }(b)-1}$ and replacing $P_{b i r t h(a b)}=a b$ with $v b$.
(C) $\operatorname{birth}(a)=\operatorname{birth}(b)$

Let $a^{\prime}$ and $b^{\prime}$ be the endpoints of $P_{\text {birth }(b)}$ such that $a^{\prime}$ is closer to $a$ than to $b$ on $P_{\text {birth(b) }}$. We assume w.l.o.g. that $w \neq a^{\prime}$, as otherwise, by symmetry, $\left\{a^{\prime}, a\right\}$ can
be replaced with $\left\{b^{\prime}, b\right\}$ and vice versa. Let $Z_{1}=a v \cup v w \cup P_{\text {birth }(b)}\left[a^{\prime}, a\right]$ and $Z_{2}=P_{b i r t h(b)}\left[a, b^{\prime}\right]$. Obtain $D^{\prime}$ from $D$ by replacing $P_{\text {birth }(b)}$ with the two ears $Z_{1}$ and $Z_{2}$ in that order and replacing $P_{\text {birth }(a b)}=a b$ with $v b$.
(iii) $\operatorname{birth}(w)=\operatorname{birth}(b) \quad \triangleright w \in \operatorname{inner}\left(P_{\text {birth }(b)}\right)$ and $w \notin\{a, b\}$ If $\operatorname{birth}(a)=\operatorname{birth}(b)>0$, let $a^{\prime}$ and $b^{\prime}$ be the endpoints of $P_{\operatorname{birth}(b)}$ such that $a^{\prime}$ is closer to $a$ than to $b$ on $P_{b i r t h(b)}$. We distinguish the following subcases.
(A) $\operatorname{birth}(a)=\operatorname{birth}(b)>0$ and $w$ lies strictly between either $a$ and $a^{\prime}$ or $b$ and $b^{\prime}$ in $P_{\text {birth(b) }}($ say w.l.o.g. between b and b')
Let $Z_{1}=a v \cup v w \cup P_{\text {birth }(b)}\left[a^{\prime}, a\right] \cup P_{\text {birth }(b)}\left[w, b^{\prime}\right]$ and let $Z_{2}=P_{\text {birth }(b)}[a, w]$. Obtain $D^{\prime}$ from $D$ by replacing $P_{\text {birth(b) }}$ with the two ears $Z_{1}$ and $Z_{2}$ in that order and replacing $P_{b i r t h(a b)}=a b$ with $v b$.
(B) $\operatorname{birth}(a)=\operatorname{birth}(b)>0$ and $w$ lies strictly between $a$ and $b$ in $P_{\text {birth(b) }}$

Let $Z_{1}=a v \cup v b \cup P_{\text {birth }(b)}\left[a^{\prime}, a\right] \cup P_{\text {birth }(b)}\left[b, b^{\prime}\right]$ and let $Z_{2}=P_{\text {birth }(b)}[a, b]$. Obtain $D^{\prime}$ from $D$ by replacing $P_{\text {birth }(b)}$ with the two ears $Z_{1}$ and $Z_{2}$ in that order and replacing $P_{\text {birth(ab) }}=a b$ with $v w$.
(C) $\operatorname{birth}(a)=\operatorname{birth}(b)=0$

Consider the three edge-disjoint paths from $a$ to $w$, from $w$ to $b$ and from $b$ to $a$ in the cycle $P_{\text {birth }(b)}$. At least one of these paths must contain $r$; let $Z$ be the union of the other two paths. Obtain $D^{\prime}$ from $D$ by replacing $Z$ in $P_{0}$ with the two edges connecting $v$ to the endpoints of $Z$, adding the new ear $Z$ directly after $P_{0}$ and replacing $P_{\text {birth }(a b)}=a b$ with the edge connecting $v$ to the vertex in $\{a, b, w\}$ that is not an endpoint of $Z$.
(D) $\operatorname{birth}(a)<\operatorname{birth}(b)$

Let $b^{\prime}$ and $b^{\prime \prime}$ be the two endpoints of $P_{\text {birth(b) }}$ such that $b^{\prime}$ is closer to $w$ than to $b$ on $P_{\text {birth }(b)}$. Let $Z_{1}=P_{\text {birth }(b)}\left[w, b^{\prime}\right], Z_{2}=P_{\text {birth }(b)}\left[w, b^{\prime \prime}\right], Z_{3}=P_{\text {birth }(b)}\left[b, b^{\prime}\right]$ and $Z_{4}=P_{\text {birth }(b)}\left[b, b^{\prime \prime}\right]$. If $b^{\prime} \neq a$, obtain $D^{\prime}$ from $D$ by replacing $P_{\text {birth }(b)}$ with the two ears $a v \cup v w \cup Z_{1}$ and $Z_{2}$ in that order and replacing $P_{\text {birth }(a b)}=a b$ with $v b$. If $b^{\prime}=a$, obtain $D^{\prime}$ from $D$ by replacing $P_{\text {birth(b) }}$ with the two ears $a v \cup v b \cup Z_{4}$ and $Z_{3}$ in that order and replacing $P_{\text {birth }(a b)}=a b$ with $v w$.
(3) $\Gamma$ is an edge-edge-addition (if birth $(d)=\operatorname{birth}(b)$ and there is an edge st $\in\{a b, c d\}$ that satisfies $\operatorname{birth}(s)<\operatorname{birth}(t)$, we assume w.l.o.g. that ab is such an edge).
(a) $\operatorname{birth}(b)=\operatorname{birth}(a b)$
(i) $\operatorname{birth}(d)<\operatorname{birth}(b) \quad \triangleright d \in G_{b i r t h(b)-1}$ and $\operatorname{birth}(b)>0$ Let $a^{\prime}$ and $b^{\prime}$ be the endpoints of $P_{\text {birth(b) }}$ such that $a^{\prime}$ is closer to $a$ than to $b$ on $P_{\text {birth(b) }}\left(a^{\prime}\right.$ may be $a$, but $\left.b^{\prime} \neq b\right)$. Let $Z$ be the path obtained from $P_{\text {birth }(b)}$ by replacing $a b$ with $a v \cup v b$. Let $Z_{1}$ be the $a^{\prime} w$-path in $Z \cup v w$ and let $Z_{2}=Z\left[v, b^{\prime}\right]$.
(A) $\operatorname{birth}(c d)<\operatorname{birth}(b)$

We distinguish two cases. If $P_{\text {birth }(c d)}=c d$, obtain $D^{\prime}$ from $D$ by deleting $P_{\text {birth }(c d)}$ and replacing $P_{\text {birth(b) }}$ with the three ears $c w \cup w d, Z_{1}$ and $Z_{2}$ in that order. If $P_{\text {birth }(c d)}$ is long, obtain $D^{\prime}$ from $D$ by subdividing $c d \in P_{\text {birth(cd) }}$ with $w$ and replacing $P_{\text {birth }(b)}$ with the two ears $Z_{1}$ and $Z_{2}$ in that order.
(B) $\operatorname{birth}(c d)>\operatorname{birth}(b)$ and $P_{b i r t h(c d)}=c d$

Obtain $D^{\prime}$ from $D$ by deleting $P_{b i r t h(c d)}=c d$ and replacing $P_{b i r t h(b)}$ with the three ears $c w \cup w d, Z_{1}$ and $Z_{2}$ in that order.
(ii) $\operatorname{birth}(d)=\operatorname{birth}(b)$

$$
\triangleright d \in \operatorname{inner}\left(P_{\text {birth }(b)}\right)
$$

(A) $c \notin P_{b i r t h(b)}$

We have $\operatorname{birth}(b)>0$ and $P_{b i r t h(c d)}=c d$. Let $Z$ be the path obtained from $P_{\text {birth(b) }}$ by replacing $a b$ with $a v \cup v b$. Let $a^{\prime}$ and $b^{\prime}$ be the endpoints of $P_{\text {birth(b) }}$
such that $a^{\prime}$ is closer to $v$ than to $d$ on $Z$. Let $Z_{1}$ be the $a^{\prime} c$-path in $Z \cup v w \cup w c$ and let $Z_{2}=Z\left[v, b^{\prime}\right]$. If $b \neq u$ or $c \neq r$, obtain $D^{\prime}$ from $D$ by replacing $P_{\text {birth }(b)}$ with the two ears $Z_{1}$ and $Z_{2}$ in that order and replacing $P_{b i r t h(c d)}=c d$ with the edge $w d$. Otherwise, $b=u=d$ and $r=c$. Then obtain $D^{\prime}$ from $D$ by replacing $P_{\text {birth(b) }}$ with the two ears $Z$ and $v w \cup w b$ in that order and replacing $P_{\text {birth }(c d)}=c d$ with the edge $c w$.
(B) $c \in P_{\text {birth(b) }}$ and $\operatorname{birth(b)<birth(cd)~}$

Then $P_{\text {birth }(c d)}=c d$. Let $Z$ be obtained from $P_{\text {birth(b) }}$ by replacing $a b$ with $a v \cup v b$. Let $Z_{1}$ be a shortest path in $P_{\text {birth(b) }}$ that contains $c, d$ and $v$ and that does not contain $r$ as an inner vertex (the latter is only relevant if $P_{\text {birth(b) }}$ is a cycle). Let $z$ be the inner vertex of $Z_{1}$ that is contained in $\{c, d, v\}$. Let $Z_{2}$ and $Z_{3}$ be the two paths in $Z_{1}$ from $z$ to the endpoints of $Z_{1}$ such that $Z_{3}$ is long (note that one of $Z_{2}$ and $Z_{3}$ must be long, as otherwise $\Gamma$ would not be a BG-operation). Obtain $D^{\prime}$ from $D$ by replacing the path $Z_{1}$ in $P_{\text {birth(b) }}$ with the two edges connecting $w$ to the endpoints of $Z_{1}$, adding the two new ears $Z_{2} \cup z w$ and $Z_{3}$ directly afterwards in that order and deleting $P_{b i r t h(c d)}=c d$.
(C) $c \in P_{b i r t h(b)}$ and $\operatorname{birth}(b)=\operatorname{birth}(c d)$

Then $P_{\text {birth(b) }}$ contains $a b$ and $c d$. Let $Z$ be obtained from $P_{\text {birth(b) }}$ by replacing $a b$ with $a v \cup v b$ and $c d$ with $c w \cup w d$. Let $Z_{2}$ be the $v w$-path in $Z$ (if $\operatorname{birth}(b)=0$, $Z$ is a cycle and there are two such paths; we then choose one that does not contain $r$ as an inner vertex). Let $Z_{1}$ be obtained from $Z$ by replacing $Z_{2}$ with the edge $v w$. Obtain $D^{\prime}$ from $D$ by replacing $P_{\text {birth(b) }}$ with the two ears $Z_{1}$ and $Z_{2}$ in that order.
(b) $\operatorname{birth}(b)<\operatorname{birth}(a b)$ and $P_{\text {birth }(a b)}=a b$
(i) $\operatorname{birth}(d)<\operatorname{birth}(b)$

$$
\triangleright d \in G_{b i r t h(b)-1} \text { and } \operatorname{birth}(b)>0
$$

(A) $\operatorname{birth}(a)<\operatorname{birth}(b)$ and $a b=r u$

We distinguish two cases. If $P_{\text {birth }(c d)}=c d$, obtain $D^{\prime}$ from $D$ by deleting $P_{\text {birth }(c d)}$, adding the new ears $c w \cup w d$ and $w v \cup v b$ directly before and after $P_{b i r t h(b)}$, respectively, and replacing $P_{b i r t h(a b)}=a b$ with $a v$. If $P_{b i r t h(c d)}$ is long, obtain $D^{\prime}$ from $D$ by subdividing $c d \in P_{b i r t h(c d)}$ with $w$, adding the new ear $w v \cup v b$ directly after $P_{b i r t h(b)}$ and replacing $P_{b i r t h(a b)}=a b$ with $a v$.
(B) $\operatorname{birth}(a)<\operatorname{birth}(b)$ and $a b \neq r u$

We distinguish two cases. If $P_{\text {birth }(c d)}=c d$, obtain $D^{\prime}$ from $D$ by deleting $P_{\text {birth }(c d)}$, adding the new ears $c w \cup w d$ and $a v \cup v w$ directly before $P_{\text {birth }(b)}$ in that order and replacing $P_{\text {birth }(a b)}=a b$ with $v b$. If $P_{b i r t h(c d)}$ is long, obtain $D^{\prime}$ from $D$ by subdividing $c d \in P_{\text {birth }(c d)}$ with $w$, adding the new ear $a v \cup v w$ directly before $P_{\text {birth }(b)}$ and replacing $P_{\text {birth }(a b)}=a b$ with $v b$.
(C) $\operatorname{birth}(a)=\operatorname{birth}(b)$

Let $a^{\prime}$ and $b^{\prime}$ be the endpoints of $P_{\text {birth(b) }}$ such that $a^{\prime}$ is closer to $a$ than to $b$ on $P_{\text {birth(b) }}$. Let $Z_{1}$ be the $a^{\prime} w$-path in $P_{\text {birth }(b)} \cup a v \cup v w$. Let $Z_{2}$ be the $b^{\prime} a$-path in $P_{\text {birth(b) }}$. We distinguish two cases. If $P_{\text {birth }(c d)}=c d$, obtain $D^{\prime}$ from $D$ by deleting $P_{\text {birth }(c d)}$, replacing $P_{\text {birth(b) }}$ with the three ears $c w \cup w d, Z_{1}$ and $Z_{2}$ in that order and replacing $P_{\text {birth(ab) }}=a b$ with $v b$. If $P_{b i r t h(c d)}$ is long, obtain $D^{\prime}$ from $D$ by subdividing $c d \in P_{\text {birth }(c d)}$ with $w$, replacing $P_{\text {birth(b) }}$ with the two ears $Z_{1}$ and $Z_{2}$ in that order and replacing $P_{\text {birth }(a b)}=a b$ with $v b$.
(ii) $\operatorname{birth}(d)=\operatorname{birth}(b)$

$$
\triangleright d \in \operatorname{inner}\left(P_{\text {birth }(b)}\right)
$$

In subcases A and B , we will assume that $\operatorname{birth}(a)=\operatorname{birth}(b)=\operatorname{birth}(c)$. Then also $\operatorname{birth}(d)=\operatorname{birth}(b)$. In these cases, we define $Z_{1}$ as a path in $P_{\text {birth(b) }}$ that contains all
vertices in $\{a, b, c, d\}$ and two of them as endpoints such that, if $\operatorname{birth}(b)=0$, either $r \notin Z_{1}$ or the endpoints of $Z_{1}$ contain $r$ and a vertex in $\{a, b\}$. The latter condition avoids further case distinctions and may be assumed, as either $r \in\{a, b\}$ or otherwise $r \notin\{a, b\}$, which implies that either $a$ or $b$ is closest to $r$ in $P_{0}$ among all vertices in $\{a, b, c, d\}-r$. For an arbitrary direction of $Z_{1}$, let $\left(x_{1}, \ldots, x_{4}\right)$ be the vertices $\{a, b, c, d\}$ in $Z_{1}$ in the order of occurrence. Due to the symmetry of $a$ and $b$ (and $c$ and $d$ ) in the BG-operation $\Gamma$, we can assume that $a$ precedes $b$ and $c$ precedes $d$ in this order. This gives four possibilities for $\left(x_{1}, x_{4}\right)$, which will be distinguished in the following subcases A and B. Note that all subcases satisfy $P_{\text {birth }(c d)}=c d$ when $c d \notin P_{\text {birth }}(b)$.
(A) $\operatorname{birth}(a)=\operatorname{birth}(b)=\operatorname{birth}(c)$ and $\left(x_{1}, x_{4}\right)$ is either $(a, b)$ or $(c, d)$

If $\left(x_{1}, x_{4}\right)=(c, d), c d \notin P_{\text {birth(b) }}$ follows, as otherwise $\operatorname{birth}(b)=0$ and $r$ is an endpoint of $Z_{1}$, but no endpoint of $Z_{1}$ would be in $\{a, b\}$. It follows that $\operatorname{birth}(d)<\operatorname{birth}(c d)$, which makes $(c, d)$ and $(a, b)$ interchangeable, as it was assumed that $\operatorname{birth}(b)<\operatorname{birth}(a b)$. Therefore, we can assume $\left(x_{1}, x_{4}\right)=(a, b)$ and thus $\left(x_{1}, \ldots, x_{4}\right)=(a, c, d, b)$. Since $\Gamma$ is a BG-operation, $c \neq a$ or $d \neq b$; by symmetry, we assume $d \neq b$. Let $Z_{2}$ be the $c a$-path in $Z_{1}\left(Z_{2}\right.$ may be of length 0). If $c d \in P_{\text {birth(b) }}$, let $Z_{3}$ be the $w b$-path in the path obtained from $P_{\text {birth(b) }}$ by subdividing $c d$ with $w$; otherwise, let $Z_{3}=P_{\text {birth }(b)}[c, b]$. Obtain $D^{\prime}$ from $D$ by replacing the path $Z_{1}$ in $P_{\text {birth(b) }}$ with $a v \cup v b$, adding the two ears $v w \cup w c \cup Z_{2}$ and $Z_{3}$ directly after $P_{\text {birth }(b)}$ in that order and, if $c d \notin P_{\text {birth(b) }}$, replacing $P_{\text {birth }(c d)}=c d$ with $w d$.
(B) $\operatorname{birth}(a)=\operatorname{birth}(b)=\operatorname{birth}(c)$ and $\left(x_{1}, x_{4}\right)$ is either $(a, d)$ or $(c, b)$

Then $\left(x_{1}, \ldots, x_{4}\right)$ is either $(a, b, c, d),(a, c, b, d),(c, a, d, b)$ or $(c, d, a, b)$. The last two orderings coincide with the first two ones by assuming the reverse direction of $Z_{1}$ in advance (and still assuming that $a$ precedes $b$ and $c$ precedes $d$ ). We distinguish the following two cases for each of the first two orderings. If $c d \notin$ $P_{\text {birth }(b)}$, let $Z_{2}=Z_{1}$; otherwise, let $Z_{2}$ be the $a w$-path in the path obtained from $P_{\text {birth(b) }}$ by subdividing $c d$ with $w$. Obtain $D^{\prime}$ from $D$ by replacing the path $Z_{1}$ in $P_{\text {birth(b) }}$ with $a v \cup v w \cup w d$, adding the ear $Z_{2}$ directly after $P_{\text {birth(b) }}$, replacing $P_{\text {birth }(a b)}=a b$ with $v b$ and, if $c d \notin P_{\text {birth(b) }}$, replacing $P_{\text {birth }(c d)}=c d$ with $w c$.
(C) $\operatorname{birth}(a)<\operatorname{birth}(b)$ and $c \notin P_{\text {birth(b) }}$

Then $P_{\text {birth }(c d)}=c d$ and $P_{\text {birth }(a b)}=a b$. Let $b^{\prime}$ and $b^{\prime \prime}$ be the two endpoints of $P_{\text {birth }(b)}$ such that $b^{\prime}$ is at least as close to $d$ as to $b$ on $P_{\text {birth(b) }}$ ( $a$ may be contained in $\left.\left\{b^{\prime}, b^{\prime \prime}, c\right\}\right)$. Let $Z_{1}=P_{\text {birth }(b)}\left[d, b^{\prime}\right]$ and $Z_{2}=P_{\text {birth }(b)}\left[d, b^{\prime \prime}\right]$. If $b=d$ and $r u \in\{a b, c d\}$, say $r u=a b$ by symmetry, obtain $D^{\prime}$ from $D$ by replacing $P_{\text {birth(b) }}$ with the three ears $c w \cup w d \cup Z_{1}, Z_{2}$ and $w v \cup v b$ in that order, deleting $P_{b i r t h(c d)}=c d$ and replacing $P_{b i r t h(a b)}=a b$ with $a v$. If $b=d, a b \neq r u$ and $c d \neq r u$, obtain $D^{\prime}$ from $D$ by adding the ear $a v \cup v w \cup w c$ directly before $P_{\text {birth }(b)}$, replacing $P_{\text {birth }(c d)}=c d$ with $w d$ and replacing $P_{\text {birth }(a b)}=a b$ with $v b$. Otherwise $b \neq d$. Then obtain $D^{\prime}$ from $D$ by replacing $P_{\text {birth }(b)}$ with the three ears $c w \cup w d \cup Z_{1}, a v \cup v w$ and $Z_{2}$ in that order, deleting $P_{b i r t h(c d)}=c d$ and replacing $P_{\text {birth }(a b)}=a b$ with $v b$.
(D) $\operatorname{birth}(a)<\operatorname{birth}(b), a \in P_{\text {birth(b) }}$ and $c$ and $d$ are both contained in $P_{\text {birth }(b)}[a, b]$ Then $a$ must be an endpoint of $P_{\text {birth }(b)}$ (note that $a=c$ is possible while $b=u$ is not possible). Let $b^{\prime}$ be the other endpoint of $P_{b i r t h(b)}$ and let $Z_{1}=P_{\text {birth(b) }}\left[b, b^{\prime}\right]$. By symmetry, we can assume that $a$ is closer to $c$ than to $d$ in $P_{\text {birth(b) }}$ (otherwise, swap $c$ and $d$ ). Let $Z_{2}=P_{\text {birth }(b)}[a, c], Z_{3}=P_{\text {birth }(b)}[c, d]$ and $Z_{4}=P_{\text {birth }(b)}[d, b]$.

If $a=c$, let $Z_{5}=a w \cup w v$ and let $Z_{6}$ be either $w d \cup Z_{4}$ if $c d \in P_{\text {birth(b) }}$ or $Z_{3} \cup Z_{4}$ otherwise (note $Z_{4}$ is of length at least one in this case). If $a \neq c$, let $Z_{5}=v w \cup w d \cup Z_{4}\left(Z_{4}\right.$ may be of length 0$)$ and let $Z_{6}$ be either $Z_{2} \cup c w$ if $c d \in P_{\text {birth(b) }}$ or $Z_{2} \cup Z_{3}$ otherwise. Obtain $D^{\prime}$ from $D$ by replacing $P_{\text {birth(b) }}$ with the three ears $a v \cup v b \cup Z_{1}, Z_{5}$ and $Z_{6}$ in that order, deleting $P_{\text {birth }(a b)}=a b$ and, if $c d \notin P_{\text {birth }(b)}$, replacing $P_{\text {birth }(c d)}=c d$ with the edge $w d$ if $a=c$ and with $w c$ otherwise.
(E) $\operatorname{birth}(a)<\operatorname{birth}(b), c \in P_{\text {birth(b) }}$ and either $a \notin P_{\text {birth(b) }}$ or $a$ is an endpoint of $P_{\text {birth(b) }}$ and not both, $c$ and d, are contained in $P_{\text {birth(b) }}[a, b]$
If $a b=r u$, we have $\operatorname{inner}\left(P_{\operatorname{birth}(b)}\right)=b=d$ and $c d \in P_{b i r t h(b)}$, because $D$ avoids $r u$. Then obtain $D^{\prime}$ from $D$ by subdividing $c d \in P_{\text {birth(b) }}$ with $w$, adding the ear $w v \cup v b$ directly after $P_{b i r t h(b)}$ and replacing $P_{b i r t h(a b)}=a b$ with $a v$. Otherwise $a b \neq r u$. Let $b^{\prime}$ be an endpoint of $P_{b i r t h(b)}$ that is different from $a$ such that the $b^{\prime} b$-path in $P_{\text {birth }(b)}$ contains at least one vertex in $\{c, d\}-b$. Let $s$ be the vertex in $\{c, d\}-b$ that is closest to $b^{\prime}$ on $P_{\text {birth }(b)}$ and let $b^{\prime \prime}$ be the other endpoint of $P_{\text {birth }(b) \text {. Let }} Z_{1}=P_{\text {birth }(b)}\left[b^{\prime}, s\right]\left(Z_{1}\right.$ may be of length 0$)$. If $c d \in P_{\text {birth(b) }}$, let $Z_{2}$ be the $w b^{\prime \prime}$-path in the path obtained from $P_{\text {birth(b) }}$ by subdividing $c d$ with $w$; otherwise, let $Z_{2}=P_{\text {birth(b) }}\left[s, b^{\prime \prime}\right]$. Obtain $D^{\prime}$ from $D$ by replacing $P_{\text {birth }(b)}$ with the two ears $a v \cup v w \cup w s \cup Z_{1}$ and $Z_{2}$ in that order, replacing $P_{\text {birth }(a b)}=a b$ with $v b$ and, if $c d \notin P_{\text {birth(b) }}$, replacing $P_{\text {birth(cd) }}=c d$ with the edge connecting $w$ to the vertex $\{c, d\}-s$.

## 5 Proof of the Path Replacement Lemma

It suffices to prove Lemma 17. We split the proof over the three Lemmas 18, 20 and 21. First, we observe that the cases of all types of BG-operations are mutually exclusive and complete. This is most often straight-forward; e.g. $\operatorname{birth}(b) \neq \operatorname{birth}(a b)$ in Case (2) implies $\operatorname{birth}(b)<\operatorname{birth}(a b)$ and thus $P_{\text {birth }(a b)}=a b$, as the edge $a b$ cannot be added before $a$ and $b$ have been added (recall that we assume $\operatorname{birth}(a) \leq \operatorname{birth}(b))$. For Cases (2aiii) and (2biii), recall that $w \notin\{a, b\}$, as otherwise $\Gamma$ would not be a BG-operation.

The completeness of Cases (3ai) and (3bii) needs special attention. In Case (3ai), $\operatorname{birth}(c d) \neq$ $\operatorname{birth}(b)$, as otherwise $P_{\text {birth(b) }}$ would contain $a b$ and $c d$ and have endpoints $c$ and $d$, which is clearly impossible. In Case (3bii), the subcases A and B cover the case $\operatorname{birth}(a)=\operatorname{birth}(b)$, in which we also have $\operatorname{birth}(b)=\operatorname{birth}(c)$, as $a$ and $b$ have been chosen such that $\operatorname{birth}(a)<\operatorname{birth}(b)$ if possible. Otherwise, $\operatorname{birth}(a)<\operatorname{birth}(b)$. Case (3biiC) covers $c \notin P_{\operatorname{birth}(b)}$, so that $c \in P_{\operatorname{birth}(b)}$ in the remaining two subcases. Let $R$ be the property that $a \in P_{\text {birth(b) }}$ and $c$ and $d$ are both contained in $P_{\text {birth }(b)}[a, b]$. Then Case (3biiD) covers $R$, which leaves as last subcase that either $a \notin P_{\text {birth }(b)}$ or $a \in P_{\text {birth(b) }}$ and not both, $c$ and $d$, are contained in $P_{\text {birth }(b)}[a, b]$; for the latter condition, $a$ is an endpoint of $P_{\text {birth(b) }}$, as $\operatorname{birth}(a)<\operatorname{birth}(b)$.

We now verify that $D^{\prime}$ is an ear decomposition. Since the newly added ears of every case are paths, it suffices to show that exactly the first ear of $D^{\prime}$ is a cycle. The cases in which a modification of $P_{0}$ is possible are (2ai), (2aiii), (2bi), (2biiiC), (3bi) and (3aiA) (both by modifying $P_{\text {birth }(c d)}$ ), (3aiiB +C$)$ and $(3 \mathrm{biiA}+\mathrm{B})$. All of these cases may at most subdivide $P_{0}$ by a new vertex and replace a subpath of $P_{0}$ with a shorter path having the same endpoints. Both of these modifications preserve that $P_{0}^{\prime}$ is a cycle in $D^{\prime}$. We conclude that $D^{\prime}$ is an ear decomposition.

We prove that the number of ears in $D^{\prime}$ is $m-n+2$, as claimed in Lemma 17. Since $D^{\prime}$ is an ear decomposition, there are $\left|E\left(G^{\prime}\right)\right|-\left|V\left(G^{\prime}\right)\right|+1$ ears in $D^{\prime}$ due to Whitney [21]. As applying $\Gamma$

Figure 3: Cases (1) and (2) of Lemma 17. Black vertices are endpoints of ears that are contained in $G_{b i r t h(b)}$. The dashed paths depict (parts of) the ears in $D^{\prime}$.
to $G$ increases the number of edges by exactly one more than the number of vertices, regardless of the type of BG-operation, the number of ears in $D^{\prime}$ is $m-n+2$.

The key observation for the remaining arguments is that $D^{\prime}$ is similar to $D$ with respect to long ears. It is easy to check that all modifications of ears in Cases (1)-(3) are done according to $M 1-M 4$. Note that all modifications either replace long ears with long ears or short ears with short ears. Since $M 3$ and $M 4$ deal only with short ears, the only long ears in $D$ that may be changed are $P_{\text {birth(b) }}$ due to $M 1$ and $P_{\text {birth(cd) }}$ due to $M 2$. However, $M 1$ and $M 2$ are only allowed to do local changes to the sequence of long ears. We get the following identity (ignoring $P_{\text {birth(cd) }}$ and $P_{c w d}^{\prime}$ if $\Gamma$ is an edge-vertex-addition and additionally ignoring $P_{b i r t h(b)}$ and $P_{b_{1}}^{\prime}-P_{b_{3}}^{\prime}$ if $\Gamma$ is a vertex-vertex-addition):
$\left.{ }^{*}\right)$ The sequences of long ears in $D-P_{b i r t h(b)}-P_{b i r t h(c d)}$ and $D^{\prime}-P_{b_{1}}^{\prime}-P_{b_{2}}^{\prime}-P_{b_{3}}^{\prime}-P_{c w d}^{\prime}$ are identical.

Thus, $\left({ }^{*}\right)$ determines the few long ears that may change when applying $\Gamma$, while $M 1$ and $M 2$ restrict how these changes may look like. It remains to prove that $D^{\prime}$ is non-separating and avoids $r u$ (respectively, $r v$ or $r w$ ).

Lemma 18. $D^{\prime}$ avoids ru (respectively, rv or $r w$ ).

Figure 4: Case (3) of Lemma 17.

Proof. In order to check that $D^{\prime}$ satisfies Definition $9.1\left(r \in P_{0}^{\prime}\right)$, it suffices to consider the cases in which $V\left(P_{0}\right) \nsubseteq V\left(P_{0}^{\prime}\right)$, i.e. the Cases (2aiii), (2biiiC), (3aiiB+C) and (3biiA+B). In all these cases, the new ear $P_{0}^{\prime}$ is constructed explicitly such that $r \in P_{0}$ implies $r \in P_{0}^{\prime}$, which gives the claim. It remains to check Definition 9.2. Clearly, if $\Gamma$ is a vertex-vertex-addition, $D^{\prime}$ satisfies Definition 9.2, as only a short ear is added.

Let $\Gamma$ be an edge-vertex-addition and assume first that $v$ does not subdivide $r u$. Recall that $P_{\text {birth(u) }}$ is the last long ear in $D$. If $\operatorname{birth}(u)>\operatorname{birth}(b), P_{\operatorname{birth}(u)}$ is also the last long ear in $D^{\prime}$, according to $\left(^{*}\right)$. Thus, $D^{\prime}$ satisfies Definition 9.2. Otherwise, $\operatorname{birth}(u)=\operatorname{birth}(b)$, as $P_{\text {birth }(b)}$ is long because it contains $b$ as an inner vertex. This implies $b=u$, since $u$ is the only inner vertex of $P_{\text {birth }(u)}$.

If $a \notin P_{b i r t h(b)}, \operatorname{birth}(a)<\operatorname{birth}(b)<\operatorname{birth}(a b)$ and we are in Case (2bii), as $w \in G_{b i r t h(b)}$ and $w \neq b$, the latter since $\Gamma$ is a BG-operation. Since $a \neq r$ by assumption, we are in Case (2biiB). In this subcase, $P_{\text {birth(b) }}$ is left unchanged and no long ear is added after $P_{\text {birth(b) }}$, which satisfies Definition 9.2.

If $a \in P_{\text {birth( }(b)}, a$ must be a neighbor of the inner vertex $b=u$ in $P_{\text {birth }(b)}$ and $\operatorname{birth}(a b)=\operatorname{birth}(b)$ follows. Thus, we are in Case (2aii) or (2aiii), since $w \in G_{b i r t h(b)}$. Let $b^{\prime}$ be the endpoint of $P_{\text {birth(b) }}$ different from $a$ and note that $w \neq b$. Case (2aii) adds the new ear $v u \cup u b^{\prime}$ directly after $P_{\text {birth }}(u)$. Thus, $v u \cup u b^{\prime}$ is the last long ear in $D^{\prime}$, contains exactly $u$ as inner vertex and does not contain $r u$, which satisfies Definition 9.2. In Case (2aiii) the same argument holds, as $w=b^{\prime}$.

Assume that $\Gamma$ subdivides $r u$ with $v$. This implies $a=r$ and $b=u$ with $\operatorname{birth}(a)<\operatorname{birth}(b)$, as $r \in P_{0}$ and $u \notin P_{0}$. Because $D$ satisfies Definition $9.2, a b=r u$ cannot be contained in a long ear and, hence, is itself a short ear. It follows that $\operatorname{birth}(b)<\operatorname{birth}(a b)$. Thus, we are in Case (2b). As $b=u$ is the last vertex added in $D, w \in G_{b}$. Since $w \neq b$ and $\operatorname{birth}(a)<\operatorname{birth}(b)$, we are in Case (2biiA). In this case, $w v \cup v b$ is added as last long ear in $D^{\prime}$, which satisfies Definition 9.2 for the new avoided edge $a v$ of $D^{\prime}$. Let $\Gamma$ be an edge-edge-addition and assume first that $\Gamma$ does not subdivide ru. Suppose further that $\operatorname{birth}(u)>\operatorname{birth}(b)$. If the precondition of M2 is true, $\operatorname{birth}(c d)=\operatorname{birth}(d)<\operatorname{birth}(b)$; otherwise, $P_{\text {birth }(c d)}$ is either short or $\operatorname{birth}(c d)=\operatorname{birth}(b)$. According to $\left(^{*}\right), P_{\text {birth }(u)}$ is in both cases the last long ear in $D^{\prime}$. Since $r u$ was not subdivided, $D^{\prime}$ satisfies Definition 9.2.

Suppose that $\operatorname{birth}(u)=\operatorname{birth}(b)$ (note that $\operatorname{birth}(u)<\operatorname{birth}(b)$ is not possible, as $D$ avoids $r u$ ). Then $b=u$. Let $a \notin P_{b i r t h(b)}$. Then $\operatorname{birth}(a)<\operatorname{birth}(b)<\operatorname{birth}(a b)$, which implies $P_{b i r t h(a b)}=a b$. Thus, we are in Case (3b). If additionally $d \neq b$, we are in Case (3biB). This case does neither modify $P_{\text {birth(b) }}$ nor add long ears after it. Hence, $P_{\text {birth(b) }}$ is the last long ear in $D^{\prime}$, which readily implies the claim. If $d=b, \operatorname{birth}(d)=\operatorname{birth}(b)$ and we are either in Case (3biiC) or (3biiE). In the former case, $P_{\text {birth(b) }}$ is the last long ear in $D^{\prime}$ (note that $d=b$ ), which gives the claim. In Case (3biiE), $c$ must be an endpoint of $P_{\text {birth(b) }}$ and $c d \in P_{\text {birth(b) }}$, as $b$ is the only inner vertex of $P_{\text {birth(b) }}$. Let $b^{\prime \prime}$ be the endpoint of $P_{\text {birth(b) }}$ that is different from $c$. Then $w d \cup d b^{\prime \prime}$ is the last long ear in $D^{\prime}$, which gives the claim, since $d=b=u$.

Let $a \in P_{\text {birth }(b)}$. Then $a$ is a neighbor of the inner vertex $b=u$ in $P_{b i r t h(b)}$ and $\operatorname{birth}(a b)=$ $\operatorname{birth}(b)$ follows. Thus, we are in Case (3a). Let $b^{\prime}$ be the endpoint of $P_{\text {birth(b) }}$ that is different from $a$. If $d \neq b$, we are in one of the two subcases of Case (3ai). In each of them, $v b \cup b b^{\prime}$ is the last long ear in $D^{\prime}$, which gives the claim. Otherwise, $d=b$, hence $\operatorname{birth}(d)=\operatorname{birth}(b)$, and we are in Case (3aii). If $c \in P_{\text {birth(b) }}, c=b^{\prime}$, as otherwise $\Gamma$ would not be a BG-operation. It follows that $\operatorname{birth}(b)=\operatorname{birth}(c d)$ and we are in Case (3aiiC). Then $v b \cup b w$ is the last long ear in $D^{\prime}$, which gives the claim. If $c \notin P_{\text {birth(b) }}$, we are in Case (3aiiA). Then $v b \cup b b^{\prime}$ is the last long ear in $D^{\prime}$, which gives the claim.

It remains to consider the case that $\Gamma$ subdivides $r u$. First assume that $\Gamma$ subdivides $r u$ with $v$. Then $a=r, b=u$, which implies $\operatorname{birth}(u)=\operatorname{birth}(b)$, and $\operatorname{birth}(a)<\operatorname{birth}(b)$, as $r \in P_{0}$ and
$u \notin P_{0}$. Additionally, $\operatorname{birth}(b)<\operatorname{birth}(a b)$, as otherwise $\operatorname{birth}(b)=\operatorname{birth}(a b)$ and $a b=r u$ would be contained in $P_{b i r t h(u)}$, which contradicts that $D$ avoids $r u$. In particular, $\operatorname{birth}(u)=\operatorname{birth}(b)$ and $a \notin P_{\operatorname{birth}(b)}$, as the latter would contradict $\operatorname{birth}(b)<\operatorname{birth}(a b)$. Hence, we are either in one of the Cases (3biA) and (3biiC) or in the Case (3biiE) such that $b=d, c$ is an endpoint of $P_{\text {birth }(b)}$, $a \notin P_{\text {birth(b) }}$ and $c d \in P_{\text {birth(b) }}$. All three cases construct explicitly $w v \cup v b$ as the new last long ear in $D^{\prime}$, which satisfies Definition 9.2 for the new avoided edge $r v=a v$ of $D^{\prime}$, as $a \notin\{b, w\}$.

Assume that $\Gamma$ subdivides $r u$ with $w$. Then $c=r, d=u$ and $\operatorname{birth}(c)<\operatorname{birth}(d)$ for the same reason as before. Recall that we assumed $\operatorname{birth}(d) \leq \operatorname{birth}(b)$. Since $d=u$ is inner vertex of the last long ear in $D$ according to Definition 9.2, we have $\operatorname{birth}(d)=\operatorname{birth}(b)$. According to the initial assumption made in Case (3), this implies with $\operatorname{birth}(c)<\operatorname{birth}(d)$ that $\operatorname{birth}(a)<\operatorname{birth}(b)$. Thus, we can replace $(a, b)$ and $(c, d)$ with each other such that all assumptions of Case (3) are still satisfied and apply the previous case, in which $\Gamma$ subdivides $r u$ with $v$.

In order to prove that $D^{\prime}$ is non-separating, we will use the following definition that is directly motivated by $\left({ }^{*}\right)$, and a structural lemma about the connection of long ears in $D$ and $D^{\prime}$.

Definition 19. Let $f$ be the function that assigns

- the index of every long ear in $D^{\prime}-P_{b_{1}}^{\prime}-P_{b_{2}}^{\prime}-P_{b_{3}}^{\prime}-P_{c w d}^{\prime}$ to the index of its identical counterpart in $D-P_{b i r t h(b)}-P_{b i r t h(c d)}$,
- $b_{1}, b_{2}$ and $b_{3}$ to $\operatorname{birth}(b)$ if $\Gamma$ is not a vertex-vertex-addition and
- $c w d$ to $\operatorname{birth}(c d)$ if $\Gamma$ is an edge-edge-addition and the precondition of $M 2$ is true.

Lemma 20. Let $\Gamma$ be an edge-vertex-addition. Then $P_{b_{3}}^{\prime}=P_{b_{2}}^{\prime}$ and
(1) $\operatorname{inner}\left(P_{b_{1}}^{\prime}\right) \cup \operatorname{inner}\left(P_{b_{2}}^{\prime}\right)=\operatorname{inner}\left(P_{\text {birth }(b)}\right) \cup\{v\}$
(2) $\overline{V_{f(i)}} \subseteq \overline{V_{i}^{\prime}}$ for every $i \in[0, m-n+1]$. If $i \geq b_{2}, \overline{V_{i}^{\prime}}=\overline{V_{f(i)}}$. If $i<b_{1}, \overline{V_{i}^{\prime}}=\overline{V_{f(i)}} \cup v$.
(3) $\overline{G_{f(i)}}=\emptyset$ if and only if $\overline{G_{i}^{\prime}}=\emptyset$, unless $b=u$ and $i=b_{1} \neq b_{2}$.

Let $\Gamma$ be an edge-edge-addition. Then
(4) If the precondition of $M 2$ is false, inner $\left(P_{b_{1}}^{\prime}\right) \cup \operatorname{inner}\left(P_{b_{2}}^{\prime}\right) \cup \operatorname{inner}\left(P_{b_{3}}^{\prime}\right)=\operatorname{inner}\left(P_{\text {birth }(b)}\right) \cup$ $\{v, w\}$. Otherwise, inner $\left(P_{b_{1}}^{\prime}\right) \cup \operatorname{inner}\left(P_{b_{2}}^{\prime}\right) \cup \operatorname{inner}\left(P_{b_{3}}^{\prime}\right)=\operatorname{inner}\left(P_{\text {birth }(b)}\right) \cup\{v\}$ and $w \in$ inner $\left(P_{c w d}^{\prime}\right)$.
(5) $\overline{V_{f(i)}} \subseteq \overline{V_{i}^{\prime}}$ for every $i \in[0, m-n+1]$. If $i \geq b_{3}, \overline{V_{i}^{\prime}}=\overline{V_{f(i)}}$. If $i<c w d, \overline{V_{i}^{\prime}}=\overline{V_{f(i)}} \cup\{v, w\}$. If cwd $\leq i<b_{1}, \overline{V_{i}^{\prime}}=\overline{V_{f(i)}} \cup\{v, w\}$ if the precondition of $M 2$ is false and $\overline{V_{i}^{\prime}}=\overline{V_{f(i)}} \cup\{v\}$ otherwise.
(6) $\overline{G_{f(i)}}=\emptyset$ if and only if $\overline{G_{i}^{\prime}}=\emptyset$, unless $b=u$ and either $i=b_{1} \neq b_{2}$ or $i=b_{2} \neq b_{3}$.

Proof. If $\Gamma$ is an edge-vertex-addition, it is straight-forward to check that $P_{\text {birth(b) }}$ is never replaced with three distinct ears in Case (2). Thus, $b_{3}=b_{2}$.

We prove Claims (1) and (4). First, let $\Gamma$ be an edge-vertex-addition. Since $D^{\prime}$ is an ear decomposition, every vertex of $G^{\prime}$ must occur in exactly one long ear of $D^{\prime}$ as inner vertex. According to $\left(^{*}\right)$, the only long ear in $D$ that may be modified is $P_{\text {birth }(b)}$. Additionally, inner $\left(P_{b_{1}}^{\prime}\right) \cup$ inner $\left(P_{b_{2}}^{\prime}\right) \supseteq$ $\operatorname{inner}\left(P_{\text {birth }(b)}\right)$, as the long ears in $D^{\prime}-P_{b_{1}}^{\prime}-P_{b_{2}}^{\prime}$ and $D-P_{\text {birth(b) }}$ are identical. For the same reason, the new vertex $v$ in $G^{\prime}$ has to be contained in $\operatorname{inner}\left(P_{b_{1}}^{\prime}\right) \cup \operatorname{inner}\left(P_{b_{2}}^{\prime}\right)$. Then Claim (1) follows from $V\left(G^{\prime}\right)-V(G)=\{v\}$. If $\Gamma$ is an edge-edge-addition, a similar argument gives that $\operatorname{inner}\left(P_{b_{1}}^{\prime}\right) \cup \operatorname{inner}\left(P_{b_{2}}^{\prime}\right) \cup \operatorname{inner}\left(P_{b_{3}}^{\prime}\right)$ differs from $\operatorname{inner}\left(P_{\text {birth }(b)}\right)$ by either $\{v, w\}$ (if the precondition of $M 2$ is not satisfied) or $\{v\}$ (if the precondition of $M 2$ is satisfied, which implies $w \in \operatorname{inner}\left(P_{\text {cwd }}^{\prime}\right)$ ). This proves Claim (4).

We prove Claims (2) and (5). First, let $\Gamma$ be an edge-vertex-addition. According to Observation $2, \overline{V_{i}^{\prime}}$ is the union of the inner vertices of the ears in $\left\{P_{i+1}^{\prime}, \ldots, P_{m-n+1}^{\prime}\right\}$. As short ears do not
matter, let $\left\{P_{x_{1}}^{\prime}, \ldots, P_{x_{k}}^{\prime}\right\}, x_{1}>i$, be the subset of long ears in that set. If $i \geq b_{2},\left(^{*}\right)$ implies that $\left\{P_{f\left(x_{1}\right)}, \ldots, P_{f\left(x_{k}\right)}\right\}$ is exactly the set of long ears in $D$ strictly after $P_{f(i)}$, which gives $\overline{V_{i}^{\prime}}=\overline{V_{f(i)}}$. Similarly, if $i<b_{1},\left(^{*}\right)$ and Claim (1) imply that $\overline{V_{i}^{\prime}}=\overline{V_{f(i)}} \cup v$. In the remaining case $i=b_{1} \neq b_{2}$, Claim (1) implies that $\overline{V_{i}^{\prime}}=\operatorname{inner}\left(P_{b_{2}}^{\prime}\right) \cup \overline{V_{b_{2}}^{\prime}} \supset \overline{V_{f\left(b_{2}\right)}}=\overline{V_{b}}$. Hence, $\overline{V_{f(i)}} \subseteq \overline{V_{i}^{\prime}}$ for all $i$, proving Claim (2). Let $\Gamma$ be an edge-vertex-addition. If $i \geq b_{3}$, the previous arguments imply $\overline{V_{i}^{\prime}}=\overline{V_{f(i)}}$. If $i<c w d, w \in \overline{V_{i}^{\prime}}$ and $\left(^{*}\right)$ and Claim (4) imply that $\overline{V_{i}^{\prime}}=\overline{V_{f(i)}} \cup\{v, w\}$. The existence of the vertex $\underline{w}$ in $\overline{V_{i}^{\prime}}$ for $c w d \leq i<b_{1}$ is only dependent on the precondition of $M 2$. If the precondition is false, $\overline{V_{i}^{\prime}}=\overline{V_{f(i)}} \cup\{v, w\}$; otherwise, $\overline{V_{i}^{\prime}}=\overline{V_{f(i)}} \cup\{v\}$. In the remaining case $b_{1} \leq i \leq b_{2} \neq b_{3}$, Claim (4) implies that $\overline{V_{i}^{\prime}} \supseteq \operatorname{inner}\left(P_{b_{3}}^{\prime}\right) \cup \overline{V_{b_{3}}^{\prime}} \supset \overline{V_{f\left(b_{3}\right)}}=\overline{V_{b}}$. Hence, $\overline{V_{f(i)}} \subseteq \overline{V_{i}^{\prime}}$ for all $i$, proving Claim (5).

We prove Claims (3) and (6). If $\overline{G_{i}^{\prime}}=\emptyset$, Claims (2) and (5) imply that $\overline{G_{f(i)}}=\emptyset$. Let $\overline{G_{f(i)}}=\emptyset$. Then $f(i) \geq b$, as $P_{b i r t h(b)}$ is a long ear, and it follows that $i \geq b_{1}$. If $i \geq b_{3}, \overline{G_{i}^{\prime}}=\emptyset$, according to Claims (2) and (5). Otherwise, either $i=b_{1} \neq b_{2}$ or $i=b_{2} \neq b_{3}$ (the latter is only possible if $\Gamma$ is an edge-edge-addition). In both cases, $f(i)=b$. Then $\overline{G_{b}}=\emptyset$ by assumption and it follows that $P_{\text {birth(b) }}$ is the last long ear in $D$. Because $D$ avoids $r u, b=u$, according to Definition 9.2. We conclude Claims (3) and (6).

Lemma 21. $D^{\prime}$ is non-separating.
Proof. We prove that $D^{\prime}$ satisfies Definition 9.3. Consider any $0 \leq i \leq m-n+1$ and let $z$ be any inner vertex of $P_{i}^{\prime}$. We assume that $\overline{G_{i}^{\prime}} \neq \emptyset$, as otherwise there is nothing to show.

Let $\Gamma$ be a vertex-vertex-addition. According to $\left(^{*}\right)$, the sequences of long ears in $D$ and $D^{\prime}$ are identical. Thus, $P_{f(i)}$ contains $z$ as an inner vertex and, because of Observation $2, \overline{V_{i}^{\prime}}=\overline{V_{f(i)}}$, in particular $\overline{G_{f(i)}} \neq \emptyset$. Since $D$ is non-separating, $z$ has a neighbor in $\overline{G_{f(i)}}$ and it follows that this neighbor is also contained in $\overline{G_{i}^{\prime}}$. Thus, $D^{\prime}$ satisfies Definition 9.3.

Let $\Gamma$ be an edge-vertex- or edge-edge-addition. If $z=v, i \in\left\{b_{1}, b_{2}, b_{3}\right\}$ according to Lemma $20.1+4$ and we exhibit a neighbor of $v$ in $\overline{G_{i}^{\prime}}$ in Table 1 for each subcase of Cases (2) and (3). If $z=w, i \in\left\{v w d, b_{1}, b_{2}, b_{3}\right\}$ according to Lemma 20.4 and $M 2$ and we exhibit a neighbor of $w$ in $\overline{G_{i}^{\prime}}$ in Table 1. If $b=u$ and either $i=b_{1} \neq b_{2}$ or $i=b_{2} \neq b_{3}$ (the latter is only possible if $\Gamma$ is an edge-edge-addition), $P_{b_{1}}^{\prime}$ and $P_{b_{2}}^{\prime}$ contain exactly one of the vertices $\{v, w, b\}$, as $b=u$ is the only inner vertex of $P_{b i r t h(b)}$ by Definition 9.2 for $D$. However, we have already exhibited neighbors of $v$ and $w$, so we only have to find a neighbor of $b=u=\operatorname{inner}\left(P_{i}^{\prime}\right)$ in $\overline{G_{i}^{\prime}}$ for either $i=b_{1} \neq b_{2}$ or $i=b_{2} \neq b_{3}$. Such a neighbor is given in Table 1.

In all remaining cases, $\overline{G_{f(i)}} \neq \emptyset$ due to $\overline{G_{i}^{\prime}} \neq \emptyset$ and Lemma 20.3+6. Moreover, $z$ is an inner vertex of $P_{f(i)}$, because of $\left(^{*}\right)$ and $z \notin\{v, w\}$. Since $D$ is non-separating, $z$ has a neighbor in $\overline{G_{f(i)}}$ and this neighbor is also contained in $\overline{G_{i}^{\prime}}$, according to Lemma $20.2+5$. Thus, $D^{\prime}$ satisfies Definition 9.3.

This completes the proof of Lemma 17. Every modification of Lemma 17 can be computed in constant time, as in each case only a constant number of paths is modified. We conclude the following theorem.

Theorem 22. Given an edge ru of a 3-connected graph $G$, a Mondshein sequence of $G$ avoiding ru can be computed in time $O(m)$.

## 6 Applications

Application 1: Independent Spanning Trees
Let $k$ spanning trees of a graph be independent if they all have the same root vertex $r$ and, for

| Case | Subcase | Neighbor of $v$ | Neighbor of $b$ | Neighbor of $w$ |
| :--- | :--- | :---: | :---: | :---: |
| (2ai) |  | $w$ | - |  |
| (2aii) |  | $b$ | - |  |
| (2aiii) |  | $a$ or $b$ | - |  |
| (2bi) |  | - | $v$ |  |
| (2bii) | A | $b$ | - |  |
| (2bii) | B+C | $a$ or $b$ | - |  |
| (2biii) | A | $w$ | - |  |
| (2biii) | B | inner $(Z) \cap\{a, b, w\}$ | - |  |

| (3bii) | C | $w$ | - | $c$ or $d$ |
| (3bii) | D | $b$ | $v$ | $c$ or $d$ or $v$ |
| (3bii) | E |  |  |  |

Table 1: Neighbors of $v \in \operatorname{inner}\left(P_{i}^{\prime}\right)$ and $w \in \operatorname{inner}\left(P_{i}^{\prime}\right)$ in $G_{i}^{\prime}$ and, for either $i=b_{1} \neq b_{2}$ or $i=b_{2} \neq b_{3}$, neighbors of $b=u=\operatorname{inner}\left(P_{i}^{\prime}\right)$ in $G_{i}^{\prime}$ for the proof that $D^{\prime}$ is non-separating. For entries marked with a hyphen, there is nothing to prove, as $\overline{G_{i}^{\prime}}$ is empty or the conditions for $b, u$ and $i$ do not apply.
every vertex $x \neq r$, the paths from $r$ to $x$ in the $k$ spanning trees are internally disjoint (i.e., vertex-disjoint except for their endpoints). The following conjecture from 1988 due to Itai and Rodeh [11] has received considerable attention in graph theory throughout the past decades.

Conjecture (Independent Spanning Tree Conjecture [11]). Every $k$-connected graph contains $k$ independent spanning trees.

Figure 5: Three independent spanning trees in the graph of Figure 1, which were computed from its Mondshein Sequence (vertex numbers depict the consistent st-numbering).

The conjecture has been proven for $k \leq 2$ [11], $k=3$ [4, 22] and $k=4$ [5], with running times $O(m), O\left(n^{2}\right)$ and $O\left(n^{3}\right)$, respectively, for computing the corresponding independent spanning trees. For $k \geq 5$, the conjecture is open. For planar graphs, the conjecture has been proven by Huck [10].

We show how to compute three independent spanning trees in linear time, using an idea of [4]. This improves the previous best running time by a factor of $n$. It may seem tempting to compute the spanning trees directly and without using a Mondshein sequence, e.g. by local replacements in an induction over BG-operations or inverse contractions. However, without additional structure this is bound to fail, as shown in Figure 6.

Figure 6: A spanning subgraph of a 3 -connected graph $G$. $G$ is obtained from the 3 -connected graph $G^{\prime}:=G-v \cup x y$ by a BG-operation (or inverse contraction) that adds the vertex $v$. Two of the three independent spanning trees of $G^{\prime}$ are given, rooted at $r$ (solid and dotted edges). However, not both of them can be completed to cover $v$ in $G$.

Compute a Mondshein sequence avoiding $r u$, as described in Theorem 22. Choose $r$ as the common root vertex of the three spanning trees and let $x \neq r$ be an arbitrary vertex.

First, we show how to obtain two internally disjoint paths from $x$ to $r$ that are both contained in the subgraph $G_{b i r t h(x)}$. An st-numbering $\pi$ is an ordering $v_{1}<\cdots<v_{n}$ of the vertices of a graph such that $s=v_{1}, t=v_{n}$, and every other vertex has both a higher-numbered and a lower-numbered neighbor. Let $\pi$ be consistent to a Mondshein sequence if $\pi$ is an st-numbering for every graph $G_{i}, 0 \leq i \leq m-n$. Let $t \neq u$ be a neighbor of $r$ in $P_{0}$. A consistent $t r$-numbering $\pi$ can be easily computed in linear time [3]. According to $\pi$, we can start with $x$ and iteratively traverse to a higher-numbered and lower-numbered neighbor, respectively, without leaving $G_{b i r t h(x)}$. This gives two internally disjoint paths from $x$ to $r$ and $t$; the path to $t$ is then extended to the desired path ending at $r$ by appending the edge $t r$. The traversed edges of this procedure for every $x \neq r$ give the first two independent spanning trees $T_{1}$ and $T_{2}$.

We construct the third independent spanning tree. Since a Mondshein sequence is non-separating, we can start with any vertex $x \neq r$, traverse to a neighbor in $\overline{G_{b i r t h(x)}}$ and iterate this procedure until we end at $u$. The traversed edges of this procedure for every $x \neq r$ form a tree that is rooted at $u$ and that can be extended to a spanning tree $T_{3}$ that is rooted at $r$ by adding the edge $u r . T_{3}$ is independent from $T_{1}$ and $T_{2}$, as, for every $x \neq r$, the path from $x$ to $u$ intersects $G_{b i r t h(x)}$ only in $x$.

Application 2: Output-Sensitive Reporting of Disjoint Paths
Given two vertices $x$ and $y$ of an arbitrary graph, a $k$-path query reports $k$ internally disjoint paths between $x$ and $y$ or outputs that these do not exist. Di Battista, Tamassia and Vismara [8] give data structures that answer $k$-path queries for $k \leq 3$. A key feature of these data structures is
that every $k$-path query has an output-sensitive running time, i.e., a running time of $O(\ell)$ if the total length of the reported paths is $\ell$ (and running time $O(1)$ if the paths do not exist). The preprocessing time of these data structures is $O(m)$ for $k \leq 2$ and $O\left(n^{2}\right)$ for $k=3$.

For $k=3$, Di Battista et al. show how the input graph can be restricted to be 3 -connected using a standard decomposition. For every 3 -connected graph we can compute a Mondshein sequence, which allows us to compute three independent spanning trees $T_{1}-T_{3}$ in a linear preprocessing time, as shown in Application 1. If $x$ or $y$ is the root $r$ of $T_{1}-T_{3}$, this gives a straight-forward outputsensitive data structure that answers 3-path queries: we just store $T_{1}-T_{3}$ and extract one path from each tree per query.

In order to extend these queries to $k$-path queries between arbitrary vertices $x$ and $y,[8]$ gives a case distinction that shows that the desired paths can be efficiently found in the union of the six paths in $T_{1}-T_{3}$ that join $x$ with $r$ and $y$ with $r$. This case distinction can be used for the desired output-sensitive reporting in time $O(\ell)$ without changing the preprocessing. We conclude a linear preprocessing time for all $k$-path queries with $k \leq 3$.

## Application 3: Planarity Testing

We give a conceptually very simple planarity test based on Mondshein's sequence for any 3connected graph $G$ in time $O(n)$.

The 3 -connectivity requirement is not really crucial, as the planarity of $G$ can be reduced to the planarity of all 3 -connected components of $G$, which in turn are computed as a side-product for the BG-sequence in Theorem 15; alternatively, one can use standard algorithms [9, 16] for reducing $G$ to be 3 -connected. We compute an induced Mondshein sequence $D$ avoiding an arbitrary edge $r u$ in time $O(n)$. Let $t$ be a neighbor of $r$ in $P_{0}$.

We start with a planar embedding $M_{0}$ of $P_{0}$ and assume with Observation 11 w.l.o.g. that the last vertex $u$ will be embedded in the outer face. We will first ignore short ears. Step by step, we attempt to augment $M_{i}$ with the next long ear $P_{j}$ in $D$ in order to construct a planar embedding $M_{j}$ of $G_{j}$.

Once the current embedding $M_{i}$ contains $u$, we have added all the vertices of $G$ and are done. Otherwise, $u$ is contained in $\overline{G_{i}}$, according to Definition 6.2. Then $\overline{G_{i}}$ contains a path from each inner vertex of $P_{j}$ to $u$, according to Lemma 5 . Since $u$ is contained in the outer face of the final embedding, adding the long ear $P_{j}$ to $M_{i}$ can preserve planarity only when it is embedded into the outer face $f$ of $M_{i}$. Thus, we only have to check that both endpoints of $P_{j}$ are contained in $f$ (this is easy to test by maintaining the vertices of the current outer face). If yes, we embed $P_{j}$ into $f$. Otherwise, we output "not planar"; if desired, a Kuratowski-subdivision can then be extracted in linear time.

Until now we ignored short ears, but have already constructed a planar embedding $M^{\prime}$ of a spanning subgraph of $G$. In order to test whether the addition of the short ears to $M^{\prime}$ can make the embedding non-planar, we pass through the construction of $M^{\prime}$ once more, this time adding short ears. Whenever a long ear $P_{j}$ is embedded, we test whether all short ears that join a vertex of $\operatorname{inner}\left(P_{j}\right)$ with a vertex of $G_{j-1}$ can be embedded while preserving a planar embedding. Note that if $D$ is a canonical ordering of $M, G_{j-1}$ must be 2 -connected and the outer face of $G_{j-1}$ must be a cycle, according to [18, Corollary 1.3]. The last fact allows for an easy test whether adding the short ears preserves a planar embedding.

Acknowledgments. The author wants to thank Joseph Cheriyan for valuable hints and helpfully providing a scan of his PhD-thesis and the anonymous person who drew my attention to Lee F. Mondshein's work.
