## 1. Modelling ChR2: MM Equilibration

As described in the main text, ChR2-WT and ChR2-C128T models were built using a homology model of the C1C2 chimera X-ray structure (PDB code: 3UG9) as template. From there, we set up the respective protein dimers surrounded by a POPC membrane and water molecules as solvent. The complete model is constituted by 492 amino acids ( 246 amino acids per monomer), 107 POPC molecules, and 6882 water molecules ( 6880 water molecules in ChR2-C128T, since no water molecule is expected in the DC gate of each monomer, see main text), in a box of 8.22 $\mathrm{nm} \times 6.74 \mathrm{~nm} \times 7.45 \mathrm{~nm}$.

After setting the protonation state of the protein residues (see main text), the structure of the active site was modeled taking into account previous spectroscopic and QM/MM dynamics simulations (see refs. [19-22] and references therein). More in detail, both E123 and D253 are deprotonated, and the side chain of E123 forms a hydrogen bond with the side chain of T127, allowing a water molecule to stay next to the $\mathrm{RSBH}^{+}$(Figure 1S).

The first step was the minimization of the potential energy. This was achieved by calculating 1000 steps with the steepest-descent method (tolerance of $1000 \mathrm{~kJ} \mathrm{~mol}^{-1} \mathrm{~nm}^{-1}$ ). The next step was the equilibration of the solvent, which was achieved by simulating a NVT-ensemble for 10 ps at a temperature of 300 K , applying the Berendsen thermostat [1S] (time step: 2 fs ). The heavy atoms of the protein and lipid membrane were restrained to their initial positions by harmonic potentials (force constant: $1000 \mathrm{~kJ} \mathrm{~mol}^{-1} \mathrm{~nm}^{-1}$ ). Subsequently both (wt and C218T) systems (including the protein dimer and the lipid bilayer) were equilibrated for 10 ns in the NPTensemble, at a pressure of 1 bar (Parrinello-Rahman barostat [2S]) and a temperature of 300 K (Nosé-Hoover thermostat [3S, 4 S$]$ ). The time step was set to 2 fs , using the H -bond scheme for constraints as implemented in the LINCS algorithm within the GROMACS package.

As described in the main text, MM force fields show severe shortcomings in the description of strongly hydrogen bonded networks. This has been demonstrated in particular for the BR active site. Using standard force fields, the crystal water binding to the Schiff-base NH group is lost and leaves the active site. A similar finding has been reported for ChR in our previous papers (see refs. $[18,19]$ ). If this water is lost during MM equilibration, it will not be restored in QM/MM simulations due to the limited simulation time. Therefore, to avoid a bias due to the above described 10 ns MM equilibration, we harmonically restrained the positions of the oxygen atom of the water molecule and of the nitrogen and hydrogen atoms of the $\mathrm{RSBH}^{+}$were with a force constant of $10000 \mathrm{~kJ} \mathrm{~mol}^{-1} \mathrm{~nm}^{-1}$ during the whole MM equilibration procedure. Moreover, the hydrogen bond between the hydrogen atom of T127 and the oxygen atom of E123 was constrained to a length of 0.18 nm . Note that we manually rotated the side chain of E123 and the water molecule for each monomer, therefore, the two monomers are not guaranteed to have exactly the same starting active site structure. This further results in two starting points for the production QM/MD simulations as shown in Figure 1S. The Charmm36 force field was applied
in the framework of the GROMACS software package.

Figure 1S. Initial conditions selected for MM equilibration of the proposed ChR2 models: hydrogen bonds are set between E123 and T127 side chains, and between a water molecule $\left(\mathrm{H}_{2} \mathrm{O}\right)$ and the protonated Schiff base, $\mathrm{RSBH}^{+}$ (Ret: retinal). (a) ChR2-WT, (b) ChR2-C128T. The two structures are shown in backbone colors of cyan and orange, respectively.

## 2. The DC/DT Gate Structures

For ChR2-WT, the MM equilibration simulations show two different DC gate structures: (i) one water molecule bridges D156 and C128 (water bridged DC gate, Figure 2S (a)); (ii) D156 and C128 form a direct hydrogen bond (direct DC gate, Figure 2S (b)), where D156 serves as a donor and C128 as an acceptor. In the starting structures, both monomers contain the water as shown in Figure 2S,a. During equilibration, however, the water in monomer 2 is lost, while it stays in monomer 1. The water bridged DC gate has been proposed by previous classical MD simulations [18] and validated by QM/MM vibrational frequency calculations [33]. To further check this assignment for the present models, we calculated the stretching vibrational frequency of D156 side chain ( $\nu \mathrm{COO}$ ) for the above two DC gate structures using the normal mode analysis (NMA) with the CHARMM37b1 program at the DFTB3/MM level of theory, which has been validated in detail in ref [33]. The residues C128, D156, and the bridging water molecules (for water bridged DC gate) were included in the QM region, and the rest was treated as MM part. The calculated $\nu \mathrm{COO}$ value is $1730 \mathrm{~cm}^{-1}$ for the water bridged DC gate structure, which agrees well with the experimental data $\left(1735 \mathrm{~cm}^{-1}\right)$ [5S], and $1693 \mathrm{~cm}^{-1}$ for the direct DC gate structure, i.e. $42 \mathrm{~cm}^{-1}$ red shifted compared with the FTIR value. We take this as a strong indication for the presence of one water molecule in the DC gate. The DC gate structure is strongly coupled to the active site, and the active site structures thus differ for the water bridged and direct DC gate models. Therefore, since a missing water in the DC gate may lead to wrong active site structures,
we discard the simulations of the monomer without DC water in the further analysis with QM/MM simulations.

To summarize, our findings in principle suggest that it is crucial to include the DC gate into the QM description since, in the MM description, the DC gate motif is not stable in ChR, and the bridging water tends to leave. This, however, happens during the extended MM equilibration step, which unfortunately cannot be performed using QM/MM, due to the long simulation times. Therefore, based on MM equilibration we had to discard trajectories where the water leaves the DC gate.
Regarding the $\mathrm{QM} / \mathrm{MM}$ simulations, as long as the DC gate structure is intact, the DC gate does not have to be included into the QM zone because it is far away from the counterion region. If the DC gate is broken, however, the active site structure is severely impaired. Therefore, we monitored the DC gate during the QM/MM simulations. Including the DC gate into the QM zone would increase the simulation times significantly. However, we would like to note that all calculations were performed in a QM/MM environment, therefore the Coulomb effect (which is mainly responsible for the separation of excited states) is always taken into account.
For ChR2-C128T, the simulations sample a single direct hydrogen bond between T128 and D156 (Figure 2S (c)), as discussed in a previous theoretical study [33].

Figure 2S. The DC (D156-C128)/DT (D156-T128) gate structure sampled in the present simulations. (a) water bridged DC gate of ChR2-WT; (b) direct DC gate of ChR2-WT; (c) direct DT gate of ChR2-C128T.

## 3. Modelling ChR2: QM/MM Production Run

After MM equilibration, we performed QM/MM MD simulations with the GROMACS package using DFTB3 for QM region and the Charmm36 classical force field for the remainder of the system. The QM region (S-QM) includes the retinal, Lys257, the E123, D253, and K93 side chains, and four (three for ChR2-C128T) water molecules involved in the active site hydrogen bonding patterns. Four hydrogen link atoms are needed to treat the QM/MM boundary regions where a covalent bond is involved, i.e. between $\alpha$ - and $\beta$-carbon atoms of E123, D253, K257 and K93 residues.

The restraints imposed on the active site during the MM equilibration were gradually removed
when including the active site in the QM region of the DFTB3/Charmm36 model, as summarized in Table 1S. Weak restraints on the QM waters were used in order to keep the active site intact. Otherwise, QM and MM water molecules could interchange. The constraints on the water molecules are weak ( $500 \mathrm{~kJ} \mathrm{~mol}^{-1} \mathrm{~nm}^{-1}$ ). Hence, we do not expect sensible changes if a fully relaxed model is employed, as emphasized in the manuscript.

Table 1S. Gradual (step-by-step) reduction of position restraints and distance constraints while performing QM/MM simulations. The last step (step 7) corresponds to the $\mathrm{QM} / \mathrm{MM}$ production run. The procedure required a total time of seven weeks on a single processor for each trajectory.

| Step | Simulation time $[\mathbf{p s}]$ | Position restraint on <br> non-water atoms | Distance constraint <br> (E123-T127 H-bond) | Position restraint on <br> QM water atoms <br> (only oxygen atoms) |
| :---: | :---: | :---: | :---: | :---: |
| [kJ mol $\left.\mathrm{nm}^{-1}\right]$ | Yes |  |  |  |
| Step 1 | 200 | 5000 | 500 |  |
| Step 2 | 200 | 3000 | Yes $\left.\mathrm{mm}^{-1}\right]$ |  |
| Step 3 | 200 | 2000 | Yes | 500 |
| Step 4 | 200 | 1000 | Yes | 500 |
| Step 5 | 200 | 500 | Yes | 500 |
| Step 6 | 200 | 0 | No | 500 |
| Step 7 | 1000 | 0 | No | 500 |

ChR2-WT The different DC gate structures of monomer 1 and 2 lead to different structures of the active site. This is not surprising, since a strong coupling between active site and DC gate is expected. The simulation with direct DC gate (monomer 2) shows a stable active site with $\mathrm{RSBH}^{+}-\mathrm{E} 123$ salt bridge during the entire 2 ns simulation time, which is different from the stable $\mathrm{RSBH}^{+}-\mathrm{H}_{2} \mathrm{O}$ hydrogen bonding pattern sampled by the simulations with water bridged DC gate (monomer 1). It is unclear whether monomer 1 will also sample salt-bridge structures to a larger extent. Therefore, we decided to discard the monomer 2 structure and extend the sampling of monomer 1 . We randomly selected 6 snapshots from the 2 ns trajectory with water bridged DC gate as the starting points for the production $\mathrm{QM} / \mathrm{MD}$ simulations. Additionally, to get a more accurate description of the hydrogen bond between E123 and T127, we chose a larger QM region
(L-QM), enlarging the S-QM region by including T127. This gave rise to an additional hydrogen link atom for residue T127. New velocities were generated for each simulation.

ChR2-C128T The simulations sample two E123 side chain conformations as shown in Figure 4 of the main text during the 2 ns simulation time, i.e. the E123 side chain either orients towards the cytoplasmic side or moves downwards to the extracellular side. The downshift of E123 breaks the hydrogen bond between E123 and T127 side chains. Note that one MM water molecule stays stable in the active site and forms the water cluster together with the three other QM water molecules. Considering the limitations of MM force fields in describing strong hydrogen bonds in proteins, we chose the same L-QM region on ChR2-C128T as on ChR2-WT. For statistical analysis, we randomly selected 6 snapshots from the 2 ns trajectory of each simulation as the starting points for the production QM/MD simulations.

The results in the main text are based on the simulations with L-QM for both ChR2-WT and ChR2-C128T.

13-cis,15-syn Retinal The chemical structures of all-trans retinal and 13-cis, 15-syn retinal are shown in Figure 3S (a) and (b), respectively. The cis retinal from BR (PDB code: 1X0S) was aligned to the all-trans retinal to build the cis retinal bound ChR2-WT and ChR2-C128T structures. The $\mathrm{RSBH}^{+}$has similar positions in the all-trans retinal bound complex and the 13cis, 15-syn retinal bound complex as shown in Figure 3S (c). The snapshots used for aligning were randomly selected from the all-trans retinal trajectories with L-QM. After replacing with cis retinal, the protein and the water environment were equilibrated with position restraints (force constant: $1000 \mathrm{~kJ} \mathrm{~mol}^{-1} \mathrm{~nm}^{-1}$ ) on the retinal, K93, E123, T127, D253, and four water molecules involved in the active site hydrogen bonding patterns, to remove the inappropriate atomic conflicts. The equilibration was performed at the MM level of theory using the steepest descent method. The obtained structures were used as starting points for the production QM/MD simulations with the L-QM region.

BR For comparison and to compute the excitation energy shifts, we performed a 1 ns QM/MM simulation of the BR ground state, using a starting structure from our previous study [9]. BR shows a very stable and distinct active site structure, the famous pentagonal water cluster as shown in Figure 1. As we have shown in our earlier publications [58], QM/MM MD simulations only show vibrations around this stable ground states structure, no other local minima occur. Therefore, the amount of sampling to cover this phase-space is much reduced with respect to ChR, where we have shown the large structural heterogeneity. Therefore, the sufficient sampling must assure that the trajectories visit the different local minima sufficiently, in order to converge the statistics. So the BR active site structure is suitably sampled within 1 ns simulation (1000 snapshots).

Figure 3S. The chemical structures of (a) all-trans retinal and (b) 13-cis, 15-syn retinal. (c) The alignment of the 13cis, $15-$ syn retinal (orange backbone) to the all-trans retinal (cyan backbone) shows that the RSBH $^{+}$has similar positions in the protein. The water molecules are shown in orange and cyan balls, respectively.

Simulations at 100K In solid state NMR studies at 100 K [16], the authors observed a shorter distance between $\mathrm{RSBH}^{+}$and counterion in ChR2 than in BR, which is in conflict with our results at $300 \mathrm{~K}: \mathrm{BR}(3.83 \AA)$ and $\mathrm{ChR} 2(3.82 \AA)$ have almost the same $\mathrm{RSBH}^{+}$-counterion distance. Nevertheless, a previous study by our group on BR showed a different active site at low temperature with respect to that at room temperature.[38] To get an insight into the temperature dependence of our system, we therefore performed also simulations at 100 K .

We selected 14 snapshots carrying the three hydrogen bonding patterns and two E123 side chain conformations (see main text for details), from the all-trans retinal bound ChR2-WT production trajectories. They were used as starting points of 14 independent cooling simulations of 1 ns each. The system was cooled down from 300 K to 100 K within 10 ps , and maintained at 100 K during the remaining simulation time. The same $\mathrm{QM} / \mathrm{MM}$ setups as for the 300 K production simulations in the main text were adopted.

Table 2S. Summary of structural motifs at 300 K (beginning of the simulation) and after the cooling process at 100K.

## 4. SORCI vs OM2/MRCI: Excitation Energies

The SORCI calculations at 50 QM/MM optimized ChR2-WT geometries reveal a major difference in the electronic excited-state description with respect to BR: for both BR and ChR2 (WT and -C128T) the optically-bright electronic transition is a ${ }^{1}\left(\pi, \pi^{*}\right)$ transition, but while in BR it is always a $S_{0} \rightarrow S_{1}$ vertical excitation, in ChR2 it corresponds to a $S_{0} \rightarrow S_{1}$ or to a $S_{0} \rightarrow S_{2}$ vertical excitation. In ChR2, $S_{1}$ is described - for some of the sampled structures - by a double ${ }^{1}\left(\pi, \pi^{*}\right)$ transition (i.e. a transition involving the promotion of two electrons from bonding to antibonding $\pi$ orbitals) associated with a low oscillator strength (optically dark electronic transition). The corresponding double ${ }^{1}\left(\pi, \pi^{*}\right)$ transition corresponds always to $S_{2}$ in BR. This inversion between the $S_{1}$ and $S_{2}$ electronic states may be due to the different active site structure, as already been suggested to explain the hypsochromic absorption shift of ChR2 with respect to BR (as discussed in the main text). Moreover, it may lead to a different description of the trans-to-cis photoisomerization process. In the main text, the optically bright electronic transition was always taken into account to calculate the absorption spectra. Therefore, all SORCI calculations were performed with three roots $\left(\mathrm{S}_{0}, \mathrm{~S}_{1}\right.$ and $\left.\mathrm{S}_{2}\right)$. In order to test the validity of this approach, we show here (Table 2S) the effect of the number of roots on the energy and oscillator strength of the lowest-lying optically bright electronic transition. Two ChR2-C128T models with different active site structures were tested. As it can be seen, the increase of the number of calculated excitation states does not have much influence on the single excitation energy, hence validating our approach.

Table 4S. Single-point excitation energy ( $E$ ) and oscillator strength ( $f_{\text {osc }}$ ) of the lowest-lying optically bright electronic transition, when including 3 to 6 roots (including the ground state). Two ChR2-C128T geometries were tested. Level of theory: SORCI, complete active space of 12 electrons in 12 orbitals, split-valence basis set def2SV(P).

| Geometry 1 |  |  | Geometry 2 |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{N}_{\text {root }}$ | $E / \mathrm{eV}(\mathrm{nm})$ | $f_{\text {osc }}$ | $\mathrm{N}_{\text {root }}$ | $E / \mathrm{eV}(\mathrm{nm})$ | $f_{\text {osc }}$ |
| 3 | $2.61(476)$ | 1.83 | 3 | $2.98(416)$ | 1.98 |
| 4 | $2.64(469)$ | 1.84 | 4 | $3.01(412)$ | 2.05 |
| 5 | $2.69(461)$ | 1.86 | 5 | $3.00(413)$ | 2.03 |
| 6 | $2.59(478)$ | 1.79 | 6 | $3.00(412)$ | 1.89 |

For the sake of comparison, OM2/MRCI calculations were performed at the same $50 \mathrm{QM} / \mathrm{MM}$ optimized ChR2-WT geometries as in the SORCI case using the same QM region. The OM2/MRCI calculations employed closed-shell molecular orbitals (MOs) and an active space of 20 electrons in 20 MOs (i.e. the 10 highest occupied MOs and the 10 lowest unoccupied MOs). The reference configurations comprised the closed-shell ground-state configuration and four configurations generated by excitations from the two highest occupied MOs $(\pi, \pi-1)$ to the two lowest unoccupied MOs $\left(\pi^{*}, \pi^{*}+1\right)$, i.e. the single excitations $\pi \rightarrow \pi^{*}$ and $\pi-1 \rightarrow \pi^{*}+1$ as well as the double excitations $(\pi, \pi) \rightarrow\left(\pi^{*}, \pi^{*}\right)$ and $(\pi, \pi-1) \rightarrow\left(\pi^{*}, \pi^{*}+1\right)$. All single and double excitations from the reference configurations were included in the MRCI calculations. The same MRCI treatment was applied in the single-point calculations at the snapshot geometries extracted from the $\mathrm{QM} / \mathrm{MM}$ MD simulations (see main paper).

The cross-correlation function between the SORCI and OM2/MRCI results is shown in Figure 4 S , and the simulated absorption spectra are compared in Figure 5S. The relative intensity of each histogram in Figure 5S is calculated as the normalized count of geometries in a defined energy window, multiplied by the average oscillator strength within the same energy window. The energy of each single-point excitation energy can be found in Table 3S. We conclude that a shift of the OM2/MRCI spectra by ca. 0.3 eV can almost quantitatively reproduce the SORCI spectra.

Figure 4S. Cross-correlation function between SORCI and OM2/MRCI excitation energies for the optically-bright electronic transitions. $\mathrm{R}^{2}=0.832$.

Figure 5S. Simulated ChR2-WT absorption spectra at the SORCI and OM2/MRCI levels of theory. The two histograms are centered at 2.9 and 3.2 eV , respectively (energy shift of ca. 0.3 eV ).

Table 5S. Single-point excitation energies from SORCI and OM2/MRCI calculations (unit: eV).

The computed excitation energies depend on the bond length alternation (BLA) of formal carbon-carbon single and double bonds within the polyene chain of the retinal chromophore, both for SORCI and OM2/MRCI (Figure 6S). As expected, the larger the BLA the higher the excitation energy.

Figure 6S. Dependence of the excitation energy on the retinal bond length alternation (BLA).

Different QM regions were tested with the OM2/MRCI method, in order to establish the most convenient model to be used for the calculation of the OM2/MRCI absorption spectra (Figure 7S). As shown, realistic $\mathrm{QM} / \mathrm{MM}$ results can be obtained already when only the retinal chromophore is included in the QM region; this was therefore selected as OM2/MRCI QM/MM setup.

Figure 7S. OM2/MRCI absorption spectra calculated with different QM regions: (a) retinal, four water molecules, E123 and D253 side chains (i.e. same as SORCI); (b) only retinal; (c) retinal and D253 side chain; (d) retinal and E123 side chain; (e) retinal and water.

## 6. Metadynamics

The dihedral angle around the $\mathrm{C}_{\beta}-\mathrm{C}_{\gamma}$ bond was used as the collective variable (i.e. the reaction coordinate). The parameters were set as follows: Gaussian height of $0.2 \mathrm{kcal} / \mathrm{mol}$, Gaussian width of 0.2 rad , Gaussian depositing frequency of 2 ps (1000 time steps), bias factor of 4 , and temperature of 300 K . The convergence of the metadynamics simulation was evaluated by comparing the free energy as a function of the collective variable at different times, as shown in Figure 8 S. The similar profiles obtained after 85 ns indicates a good convergence of the simulation.

Figure 8S. The free energy as a function of the dihedral angle around the $\mathrm{C}_{\beta}-\mathrm{C}_{\gamma}$ bond of E123 every 5 ns along the 100 ns well-tempered metadynamics simulation. (a) ChR2-WT bound with all-trans retinal; (b) ChR2-WT bound with 13-cis, 15-syn retinal; (c) ChR2-C128T bound with all-trans retinal; (d) ChR2-C128T bound with 13-cis, 15syn retinal.

## 7. Gaussian Fit Parameters

The analytic fitted Gaussian function parameters used to convolute the OM2/MRCI histograms, shown in Figures $7-9$ of the main text, are listed in Tables 4S.

Table 6S. Fitting parameters used to convolute the OM2/MRCI histograms into Gaussian functions of Figures 7-9 in the main text.

| Fit function: $\mathrm{y}=-\mathrm{A} 0 * \exp \left(\mathrm{~A} 2 *(\mathrm{~A} 1-\mathrm{x})^{\wedge} 2\right)$ |  |  |  |  |
