

Investigating the neural mechanisms of syntactic expectations

Leon O.H. Kroczek, Angela D. Friederici & Thomas C. Gunter

Department of Neuropsychology, Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, Germany kroczek@cbs.mpg.de

Introduction

- Languages have dominant word orders¹ that allow listeners to build expectations about the structure of an upcoming sentence², making language processing more efficient
- Expectancy is therefore a potential confound in studies relating to syntactic complexity, because complex sentences are typically less frequent (i.e. unexpected) and vise versa
- We implemented a paradigm in which the expectation for a word order was coupled to speaker identity by manipulating the speaker-specific probability of a particular word order
- This paradigm allows to distinguish between the processing of syntactic complexity and the processing of syntactic expectations
- Ambiguous probe trials were used to measure top-down expectations both on a behavioral and on a neural level

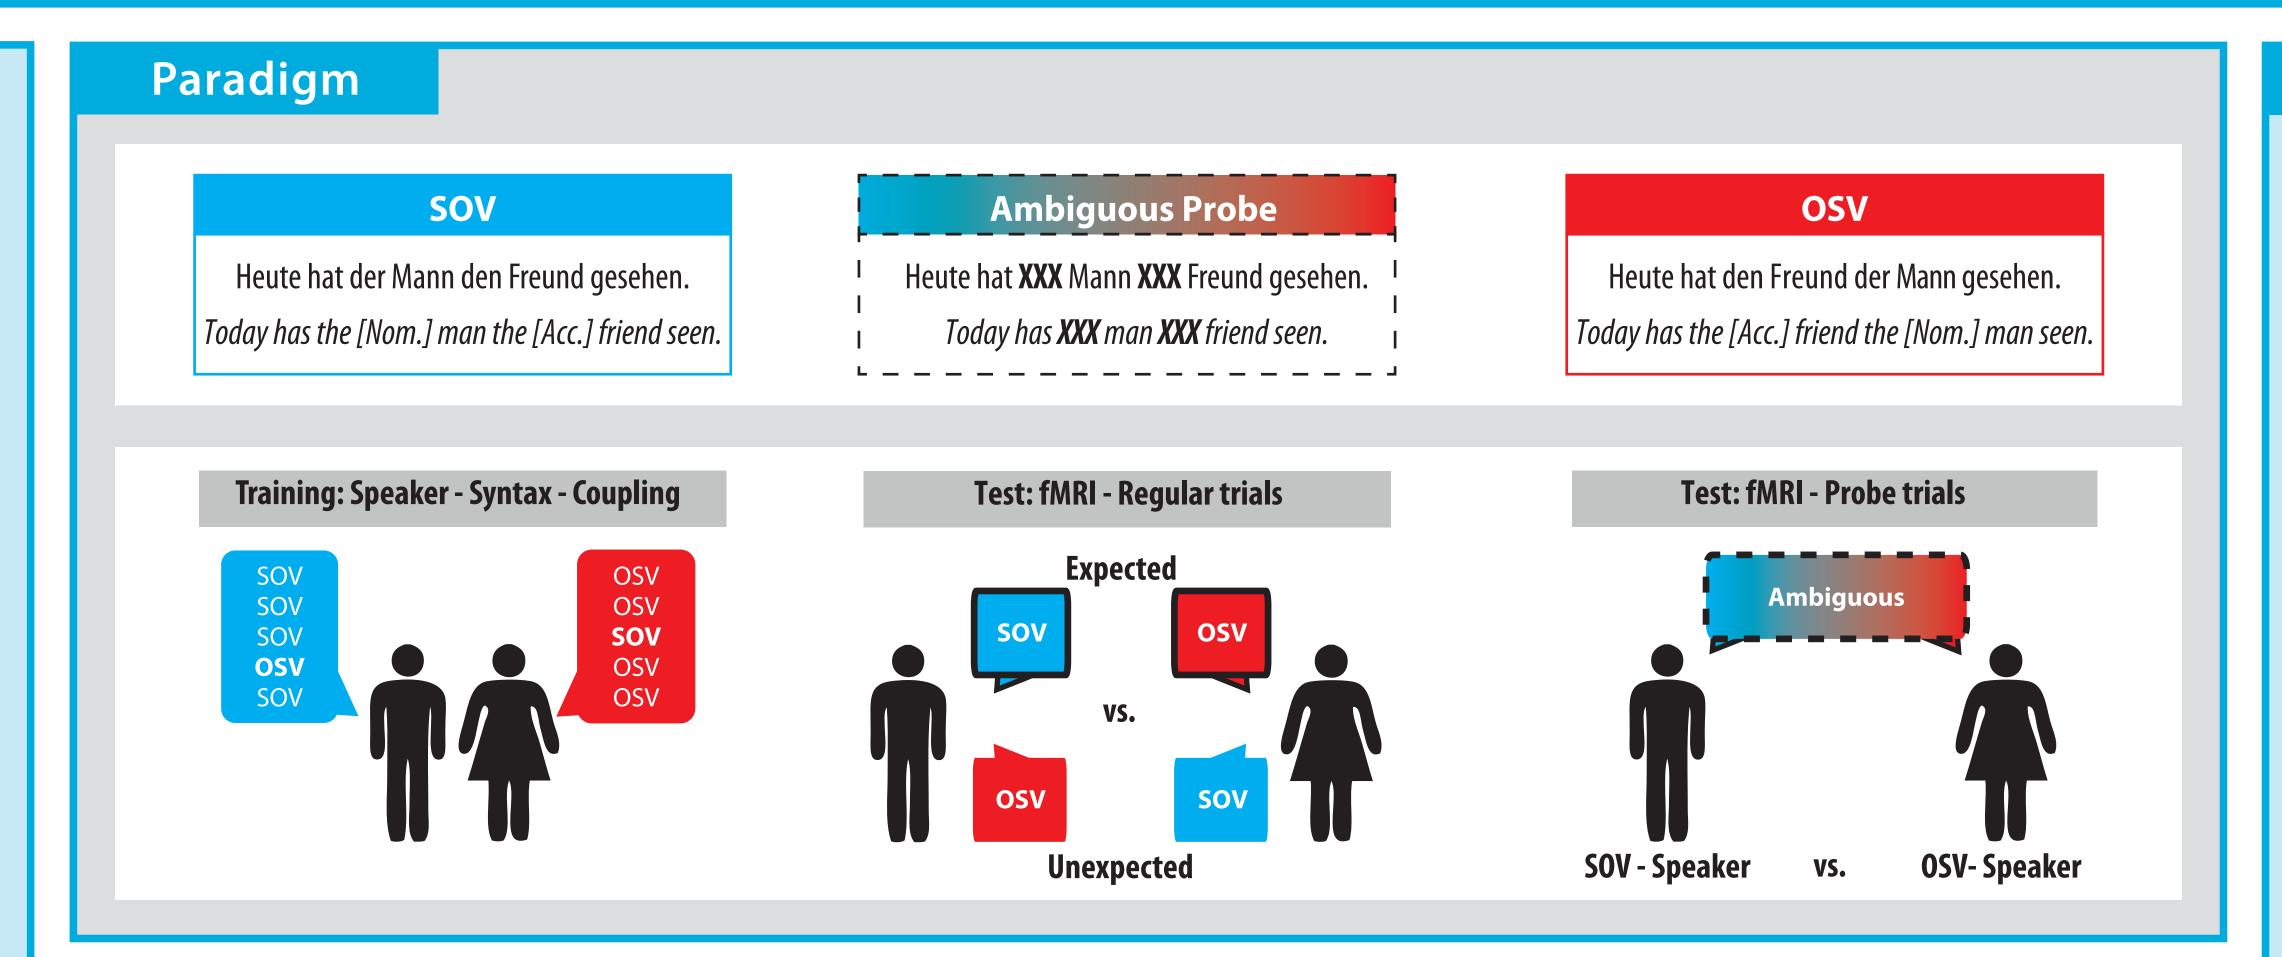

Research questions

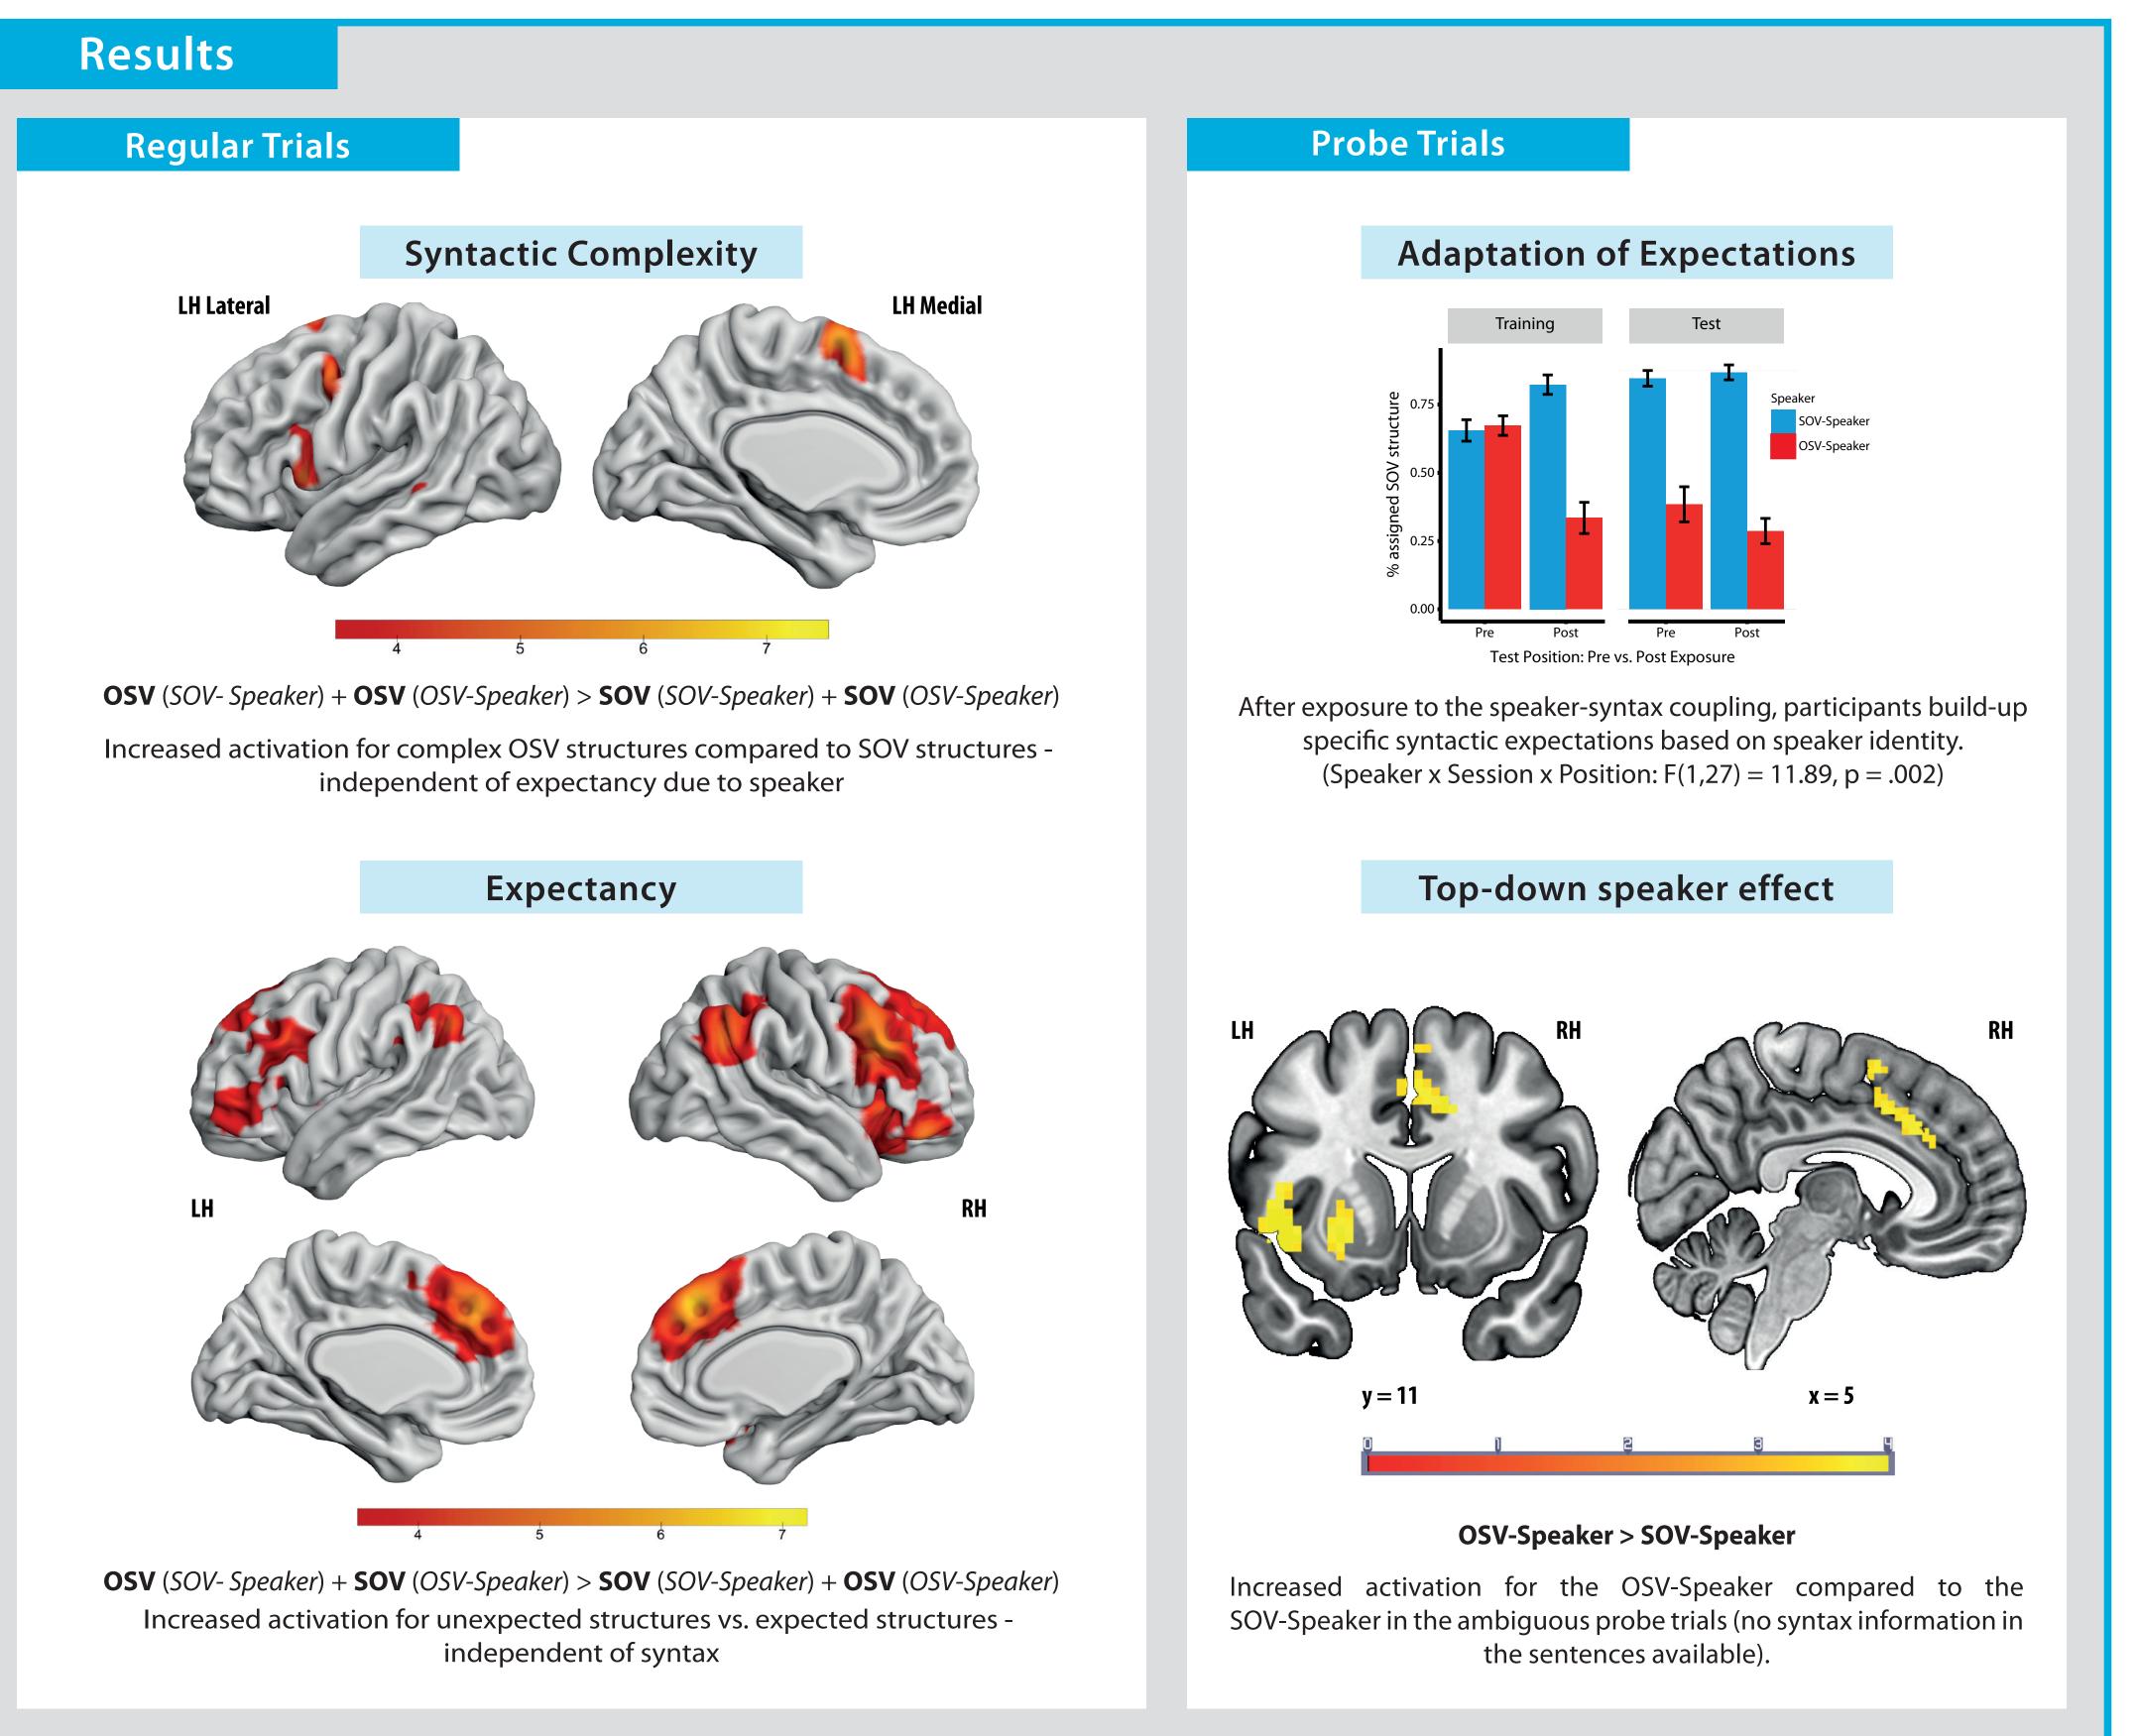

Is there a functional differentiation between syntax and expectancy?

How are top-down expectations for syntax implemented in the brain?

Methods

- Twenty-eight right-handed, native German participants completed a training session and a testing session on two consecutive days
- In regular trials, sentences had either an easy Subject-Object-Verb (SOV) or a complex Object-Subject-Verb (OSV) structure. In probe trials, sentences were syntactically ambiguous (determiners replaced with noise)
- Two speakers (male/female) were operationalized as **SOV-Speaker** (high-frequent SOV vs. low-frequent OSV) or **OSV-Speaker** (high-frequent OSV vs. low-frequent SOV). Speaker gender was balanced across participants
- Speaker-syntax coupling was established in the regular trials during the exposure phase. Speaker-specific expectations were monitored via probe trials
- In these probe trials, participants had to select the subject/object in a comprehension task. This allowed to infer whether a sentence was interpeted as SOV or OSV
- The Test Session was conducted inside the MRI-scanner (3-Tesla, Preprocessing and Analysis in SPM12, Clusters are FWE-corrected p < .05, cluster-forming-threshold p < .001)

Discussion

- Listeners adapted their synatctic expectations to the individual language use of a particular speaker
- We observed separate networks for syntactic complexity processing and the processing of expectancy based on speaker identity.
- Syntactic complexity effect was located in left-lateralized fronto-temporal regions (IFG pars opercularis, pMTG, premotor cortex, preSMA). Especially the left IFG and pMTG have been related to core linguistic computations of syntactic structure processing³
- Unexpected structures showed increased activation in a bilateral fronto-parietal network compared to expected structures (IFG pars orbitalis, MFG, Angular gyrus, preSMA, right IFG pars triangularis). This network might be related to pragmatic integration of speaker and syntax⁴
- Top-down effects in the absence of syntactic structure information (probe trials) were observed in cortical and sub-cortical areas including left Insula, left Putamen and ACC/preSMA. This regions possibly support controlled syntactic processing by means of re-sequencing^{4,5}

Conclusion

Separate networks for linguistic syntax processing and para-linguistic expectations based on speaker identity

Syntactic complexity processing in a left-lateralized fronto-temporal network

Higher-order integration of speaker-identity and syntactic information in a bilateral, right-dominant fronto-parietal network

Top-down effects of syntactic expectations are supported by cortical and subcortical brain regions underlying controlled syntactic processing
