## 1. Computational methods

Density functional theory (DFT) was used to elucidate the mechanism of the Ru (II) catalyzed hydrogenation of alkynes. All geometry optimizations were performed using the M06 ${ }^{1}$ functional. The triple- $\zeta$ quality def2-TZVP ${ }^{2}$ basis set was used for all atoms. The 28 inner-shell core electrons of the ruthenium atom were described by the corresponding def2 effective core potential ${ }^{3}$ accounting for scalar relativistic effects (def2-ecp).

Stationary points were characterized by evaluating the harmonic vibrational frequencies at the optimized geometries. Zero-point vibrational energies (ZPVE) were computed from the corresponding harmonic vibrational frequencies without scaling. Relative free energies $(\Delta G)$ were determined at standard pressure ( 1 bar ) and at room temperature ( 298 K ). The thermal and entropic contributions were evaluated within the rigid-rotor harmonic-oscillator approximation. Solvation contributions were included for dichloromethane on the optimized gas-phase geometries employing the SMD solvation model ${ }^{4}$ using the same functional and basis set. All calculations were performed using Gaussian09 with the ultrafine grid. ${ }^{5}$

Energies derived from coupled cluster theory were obtained using the domain-based pair natural orbital coupled cluster method with single and double excitations, DLPNO-CCSD, and with a perturbational estimate of the triples contributions, $\operatorname{DLPNO}-\operatorname{CCSD}(\mathrm{T})$. The def2-TZVP ${ }^{2}$ basis set was used for all atoms in conjunction with the resolution of identity approximation ${ }^{6}$ applying the RIJCOX method. ${ }^{7}$ The 28 inner-shell core electrons of the ruthenium atom were described by the corresponding def2 effective core potential ${ }^{3}$ accounting for scalar relativistic effects (def2-ecp). All coupled cluster calculations were performed using Orca 4.0. ${ }^{8}$

## 2. DFT results

The Supporting Information of our previous communication ${ }^{9}$ documents the Cartesian coordinates of all relevant optimized geometries as well as all relevant DFT-based energies and energy corrections required to evaluate free energies. These data are not presented again here.

## 3. $\operatorname{CCSD}$ and $\operatorname{CCSD}(\mathrm{T})$ results

Single-point CCSD and $\operatorname{CCSD}(\mathrm{T})$ calculations were performed at the DFT-optimized geometries of all stationary points in the hydrogenation reactions of 2-butyne with the neutral Ru (II) catalyst. Table S1 lists the calculated total and relative energies (DFT, CCSD, and $\operatorname{CCSD}(\mathrm{T})$ ). Figure S 1 shows an overlay of the computed energy profiles for the reactions yielding the $E$ alkene (E2) and carbene (C2) complexes. Figures S 2 and S 3 show analogous overlays for the $\mathrm{H}_{2}$ associative pathways leading from the carbene (C2) complex to the side products, for the approach of $\mathrm{H}_{2}$ from the side of the methyl group and the ethyl group, respectively. The notation is the same as in our previous communication. ${ }^{9}$

Table S1. Total energies (atomic units), Gibbs energy corrections ( $G_{\text {corr }}$, atomic units), and relative Gibbs energies ( $\mathrm{kcal} / \mathrm{mol}$ ) for the stationary points of the investigated reactions evaluated at the DFT-optimized geometries. All energies listed are obtained in the gas phase.
