## S1 Determination of folding patterns by means of the program SHAPE

One of the first designed Lanthanide Binding Tag peptides (termed LBT in this article) ${ }^{1}$ has the aminoacid sequence (one-letter code) shown in Table S1. The Table shows several peptides able to bind lanthanides, that have highly conserved sequences, especially in three different tracts that are enriched in acidic aminoacids (aspartates and glutamines).

Table S1. Previously reported Lanthanide Binding Tags X-ray resolved crystal structures (except for2LR2 which was determined by NMR). \# of independent Ln-binding sites > 1 is due to either duplication of peptide sequences, crystallographic inequivalence or both. Green denotes conserved aminoacidos in all proteins, bold denotes coordinating residues. Note that dozen of other variations of the same sequence have been characterized as selectively binding to lanthanide ions, ${ }^{1}$ but have not been crystallized.

SHAPE software quantifies the deviation of chemical 3D structures from either ideal geometrical structures or selected structures from the user. ${ }^{7}$ In our case, we used it to compare the shape of LBTcontaining peptides previously described in the literature with each other (see Table S1). SHAPE software determines a continuous shape parameter (SP), which is mathematically defined in a way that is independent of the size of the system. By definition, the resulting value of SP is zero when the real coordinates of the metal site (problem structure, P ) show exactly the desired ideal shape, and increases with the degree of distortion of the structure. Values below 0.1 represent chemically insignificant distortions in the structure. Values larger than 3 mean important distortions, with the highest values commonly encountered being in the order of 40 .

The main object for comparison were the $\alpha$-carbons forming the backbone of each of the LBTcontaining peptides, namely LBT peptide (molecule A and B, PDB id 1TJB), dLBT-ubiquitin (molecule A and B, PDB id 2OJR), Interleukin-1 $\beta$-(S1-LBT) (PDB id 3LTQ), xq-dSE3-ubiquitin (molecule A.1, A.2, B. 1 and B.2, PDB id 3VDZ) and Z-L2LBT (PDB id 2LR2). The coordinates
for all of the proteins were extracted from the PDB files downloaded from the RCSB Protein Data Bank website (https://www.rcsb.org/pdb/).

It is observed that the aminoacidic sequence is highly similar from the first fifteen $\alpha$-carbon atoms belonging to the LBT motif in all of the examined proteins, and it is much more variable in the sixteenth and seventeenth $\alpha$-carbon atoms (table S1.1). Additionally, not all of the LBT motifs in the molecules contain seventeen $\alpha$-carbons. For this reason two different sets of calculations were carried out. Regarding the first set, only fifteen $\alpha$-carbons were taken into account (table S1.2), whereas the second one included seventeen $\alpha$-carbons when possible (table S1.3).

Table S1.1. Aminoacid sequence of the LBT motifs found in different chimeric polypeptides. For double LBT motifs the notation used the chain name in the PDB files (A or B) and a number to denote if the unit was first or second in the sequence.

The oxygen atoms forming the coordination environment for each of the LBT motifs were used for SHAPE calculations presented in Table S1.4.
In sum, the analyses of the information of the tables above is the following:
-for the 15-long peptide fragment (Table S1.2), the foldings are distorted compared with each other, but remarkably similar, considering the great difference between the aminoacid sequences, for example in the case of 1TJB vs 3VDZ:
-for the 17-long peptide fragment (Table S1.3), the folding is markedly more different, signaling that the last two aminoacids do not fold reproducibly: the maximum SP parameters double compared with the previous table: from slightly above 4 to slightly above 8
-for the 8 oxygen coordination environment (Table S1.4), the shapes are distorted but again they are remarkably similar, considering the relative freedom enjoyed by the side groups (again, the maximum SP parameters are slightly above 4); here note that 3VDZ was designed for an efficient interchange of water molecules directly coordinated to the Gd , and as a consequence its coordination environment is severely distorted (although, as seen in the tables above, the folding remains essentially the same), so we did not consider it for the comparison.

Analysing Table S1.4, it is evident that there are relatively large calculated distortions between the oxygen coordination spheres of 2OJR (both 15CA and 17CA) and 3LTQ, something striking since they share the aminoacid sequence (primary structure) of the region that actually binds to the lanthanide ion, i.e. YIDTNNDGWIEGDEL. Compared with regular distortions between crystallographically inequivalent copies of identical coordination complexes, these SP parameters are rather high, which could mean that the coordination environments are difficult to reproduce. However, here it is crucial to put these SHAPE parameters in perspective, and for that one needs to note that peptide crystallography involves an uncertainty in the atomic positions that is higher than usual in coordination chemistry. For this purposes we can take as a measure the Diffraction Precision Index (DPI) as presented by Gurusaran and coworkers. ${ }^{7}$ We employed the data analysis software accessible at the server http://cluster.physics.iisc.ernet.in/dpi/ and, as seen in Table S1.5, found that the DPI values of the peptides under study in this section range from about 0.1 to almost $0.4 \AA$, which means the SP parameters we calculate are in this case strongly affected by crystallographic noise. Thus, these numbers should be understood as an upper limit to the real structural difference between the peptidic foldings, in the case of Tables S1.2 and S1.3, or between the coordination environments, in the case of Table S1.4. Further studies would be needed to more accurately quantify the maximum possible distortion between the coordination spheres of two lanthanide binding tags with the same primary sequence.

Table S1.5. Resolution and DPI regarding the protein structures studied.

| PDB ID | Resolution ( $\AA)$ | Diffraction Precision Index <br> DPI $(\AA)$ |
| :---: | :---: | :---: |
| 1TJB | 2.0 | 0.196 |
| 2OJR | 2.6 | 0.329 |
| 3LTQ | 2.1 | 0.097 |
| 3POK | 1.7 | 0.077 |
| 3VDZ | 2.4 | 0.392 |

Additionally, a study of the geometry of octa-coordinated $\mathrm{Tb}^{3+}$ in the LBT peptide (1TJB) context was performed comparing the position of coordination oxygens to vertices in reference polyhedra predefined in the SHAPE package. The results (see Table S1.6) suggested that the LBT coordination environment does not adopt an ideal geometry, but is closely related to a square antiprism (SHAPE parameter approx. 3.6), a triangular dodecahedron (approx. 3.3) or a biaugmented trigonal prism (approx. 3.4). Note however, that these descriptions are limited in precision for the above stated reasons of crystallographic uncertainty.

Table S1.6. Geometry study of octa-coordinated lanthanide ions in an LBT unit (1TJB). SP parameters are shown. Comparisons were made with all 13 ideal geometries included as reference polyhedra for octa-coordinated metals in the SHAPE software.

## S2 Continous Wave (CW) EPR spectroscopy and pulsed EPR determination of relaxation times

EPR measurements were performed in buffer containing 10 mM HEPES at $\mathrm{pH} 7.0,100 \mathrm{mM} \mathrm{NaCl}$, $5 \mathrm{mM} \beta$-mercaptoethanol and $20 \%$ glycerol (for cryoprotection). Thorough degassing was performed on all solutions previously to the EPR measurements, with a freeze-pump-thaw procedure as described in a work from Hirsh and Brudvig. ${ }^{9}$ This is necessary since the presence of paramagnetic $\mathrm{O}_{2}$ traces significantly alters pulsed EPR results in this kind of frozen samples.

The solutions measured by EPR spectroscopy contained varying concentrations of LBT peptide (from $72 \mu \mathrm{M}$ to $144 \mu \mathrm{M}$ ) which were in excess respect to the complexing lanthanide ion.

Both continuous-wave and pulsed EPR data were recorded on an ELEXSYS E580 EPR spectrometer (Bruker) equipped with a Pulsed X-band ( 9.3 GHz cavity and resonators) operating in the range $4-300 \mathrm{~K}$. The external magnetic field $B_{0}$ can be applied in a range $0-2 \mathrm{~T}$. The pulsed XBand is equipped with a TWT (travelling wave tube) amplifier, and is able to perform pulses between 0.7 ns and $15 \mu \mathrm{~s}$ long.

The pulse sequences for the echo-induced spectra and for the experiments determining $T_{m}$ and $T_{1}$ were based on $\tau_{\pi / 2}=12 \mathrm{~ns}, \tau_{\pi}=24 \mathrm{~ns}$ pulses with a fixed interpulse delay time of $\tau=200 \mathrm{~ns}$. Rabi oscillations were acquired by long microwave field pulses of duration $t$ and subsequently recorded by spin echo. The $\tau$ pulse and the $\pi / 2-\pi$ Hahn spin-echo sequence were recorded varying the attenuation power and subsequently the oscillating magnetic field $B_{1}$. The external static magnetic field $B_{0}$ was 3480 G .
(a)

(b)

Figure S2.1. (a) Measured $M_{z}(t)$ showing the result of nutation experiments at microwave powers that are above or below values where the Rabi frequency matches the Larmor frequency of the proton (Hartmann-Hahn condition) for the sample GdLBT at 4 K and at $B_{0}=3480 \mathrm{G}$. (b) Rabi frequencies as a function of the oscillating magnetic fiekd $B_{1}$ for GdLBT. $B_{1}$ values are calculated relative to the value of $B_{1}$ at the maximum attenuation of $19 \mathrm{~dB}, \quad B_{1}=\sqrt{10^{-0.1 A} / 10^{-1.9}}$, where $A$ is the attenuation in $d B$. The off-linear points correspond to the Hartman-Hahn condition.

Figure S2.2. Band echo-detected EPR as a function of magnetic field for GdLBT (black line) and $G d$ without LBT (blue line) measured at 4.5 K. Pulses of 12 ns for $\pi / 2$ and 24 ns for $\pi$.

Figure S2.3. Rabi oscillations adjusting the microwave attenuation to achieve the Hartmann-Hahn condition, (i.e. the electronic Rabi frequency matches the Larmor frequency of the proton) for a Gd sample prepared without the LBT peptide, measured at 4 K and at $B_{0}=3480 \mathrm{G}$. Inset: zoom-in at Rabi oscillations for long times.

(a) continuous wave EPR, (b) echodetected EPR, (c) $T_{1}$, and (d) $T_{m}$ determination. Fitting curves are monoexponential functions with stretch $x$.

## S3 Spin energies and spin states

The energy-level scheme and the spin states of GdLBT ( $J=7 / 2$ ) in presence of a external static magnetic field were extracted from the following spin hamiltonian:

$$
\begin{equation*}
\hat{\mathrm{H}}=D\left[\hat{J}_{z}^{2}-\frac{1}{3} J(J+1)\right]+E\left(\hat{J}_{x}^{2}-\hat{J}_{y}^{2}\right)+\mu_{B} g \vec{B} \cdot \overrightarrow{\hat{J}} \tag{1}
\end{equation*}
$$

The magnetic anisotropy parameters $D, E$ and the Landé $g$ factor, which was assumed to be isotropic, were extracted from fitting the corresponding cw-EPR spectrum (see Fig. S2.4.a left panel) by using the "pepper" package of the software EasySpin. The best fit parameters found are $D$ $=546.6 \mathrm{MHz}, E=293.3 \mathrm{MHz}, g=2.00232$. We employed isotropic $D$ and $E$ strains of 50 and 10 MHz respectively.

Figure S3.1. GdLBT ( $J=7 / 2$ ) "Spin energies vs magnetic field" Zeeman diagram for a magnetic field applied along the z axis. Each one of the eight curves is really 4-fold degenerate as no hyperfine coupling was set in the cw-EPR fitting.

The energy-level scheme and the spin states of NdLBT ( $J=9 / 2$ ) in presence of an external static magnetic field were extracted from the following spin Hamiltonian:

$$
\begin{equation*}
\hat{\mathrm{H}}=D\left[\hat{J}_{z}^{2}-\frac{1}{3} J(J+1)\right]+\overrightarrow{\hat{J}} \boldsymbol{A} \overrightarrow{\hat{I}}+\mu_{B} g \vec{B} \cdot \overrightarrow{\hat{J}} \tag{2}
\end{equation*}
$$

The magnetic anisotropy parameters $D, A_{\perp}, A_{\|}$, and the Landé $g$ factor, which was assumed to be isotropic, were extracted from fitting the corresponding cw-EPR spectrum (see Fig. S2.4.a right panel) by using the "pepper" package of the software EasySpin. The best fit parameters found are $D$ $=-110 \mathrm{GHz}, A_{\perp}=1.033 \mathrm{GHz}, A_{\|}=867 \mathrm{MHz}, g=0.50232$. No strains for $D, A_{\perp}, A_{\|}, g$ were employed.

Figure S3.2. NdLBT ( $J=9 / 2, I=7 / 2$ ) "Spin energies vs magnetic field" Zeeman diagram of the ground doublet $M_{J}= \pm 9 / 2$ when the magnetic field is applied along the $z$ axis. Each component of this ground doublet is split up in the eight $M_{I}$ projections of the $N d^{3+}$ nuclear spin due to a non-zero hyperfine coupling.

Table S3. Energies, wavefunctions, $M_{J}$ and $M_{I}$ expected values at zero magnetic field of the first sixteen NdLBT spin states ("ground doblet $M_{J}= \pm 9 / 2 "$ plus "nuclear spin manifold") according to the Hamiltonian previously presented.

The fitting of the cw-EPR derivative (see Fig. S3.3) in NdLBT was performed by considering an effective spin $J=1 / 2$ and using the following spin hamiltonian in presence of an external magnetic field with anisotropic $g$ and $A$ tensors:

$$
\begin{equation*}
\hat{\mathrm{H}}=\overrightarrow{\hat{J}} \boldsymbol{A} \overrightarrow{\hat{I}}+\mu_{B} \vec{B} \cdot \boldsymbol{g} \cdot \overrightarrow{\hat{J}} \tag{3}
\end{equation*}
$$

The magnetic anisotropy parameters were extracted by using the "pepper" package of the software EasySpin. The best fit parameters found are $A_{x}=-266.7 \mathrm{MHz}, A_{y}=-1233 \mathrm{MHz}, A_{z}=-366.7 \mathrm{MHz}$, $g_{x}=0.237, g_{y}=0.1, g_{z}=3.7$. A strain of 0.6 was used in $g_{z}$.

Figure S3.3. cw-EPR derivative spectrum of NdLBT along with the corresponding fitting. See above for values of parameters.

## S4 Nuclear spin bath decoherence: theoretical calculations

Nuclear decoherence time $T_{2}{ }^{n}$ calculations were carried out by using the SIMPRE1.2 package, ${ }^{10}$ adapted to deal with randomly oriented samples (powder or solution). The calculation was performed at a static magnetic field of 0.348 T applied along the molecular easy axis which defines the z-direction, giving a qubit gap of $\Delta=9.60 \mathrm{GHz}$. This gap is close to the energy ( 9.71 GHz ) of our X-band EPR spectrometer. The resonant transition selected, i.e., the two spin states that defines the qubit, was $\left|M_{J}=-1 / 2, M_{I}=+3 / 2>\rightarrow\right| M_{J}=+1 / 2, M_{I}=+3 / 2>$. There are still three more degenerate resonant transitions since no hyperfine coupling was set in the EasySpin fit, namely, $\mid M_{J}$ $=-1 / 2, M_{I}=+1 / 2>\rightarrow\left|M_{J}=+1 / 2, M_{I}=+1 / 2>,\left|M_{J}=-1 / 2, M_{I}=-1 / 2>\rightarrow\right| M_{J}=+1 / 2, M_{I}=-1 / 2>,\right| M_{J}$ $=-1 / 2, M_{I}=-3 / 2>\rightarrow \mid M_{J}=+1 / 2, M_{I}=-3 / 2>$, and they gave very similar $\mathrm{T}_{2}{ }^{\mathrm{n}}$.

To simulate the solutions we used the PACKMOL package. ${ }^{11}$ The GdLBT molecule was placed inside a sphere of a given radius R with the molecular mass centre right at the centre of the sphere. We took water ( $80 \% \mathrm{v} / \mathrm{v}$ ) and glycerol ( $20 \% \mathrm{v} / \mathrm{v}$ ) as the only solvents, considering that concentrations of HEPES, NaCl and $\beta$-mercaptoethanol are small enough to not have a significant importance. Herein, we considered that each atom of both, the GdLBT molecule and the solvents, is a sphere of radius equal to its Van der Waals radius. Then, PACKMOL randomly fills the R-radius sphere with an appropriate number of solvent molecules until reaching their relevant concentrations. In terms of number of molecules per volume, these concentrations are: $2.474 \cdot 10^{-2}$ molecules $/ \AA^{3}$ for water and $1.266 \cdot 10^{-3}$ molecules $/ \AA^{3}$ for glycerol. The magnetic nuclei positions inside the sphere is the nuclear spin bath that we took as an input for SIMPRE1.2. The radius R that we considered were 40,50 and $60 \AA$, being the last one large enough to converge $T_{2}{ }^{n}$. The calculated values are around $300 \mu \mathrm{~s}$, indicating that nuclear-induced precessional decoherence is not the limiting mechanism that dephases qubit dynamics.

## S5 Theoretical studies with ligand field theory.

In order to understand the influence of the ligand field around the lanthanide, which will permit the manipulation of the qubit behavior, we carried out a series of first-principles calculations using the density functional theory (DFT) package SIESTA ${ }^{12}$ along with the SIMPRE code. ${ }^{13}$ This allowed us to obtain a prediction of the nature of the ground state for a set of magnetic LnLBTs.

First, we built three LBT isomers by swapping the position of the coordinating residue Asn3 by Asp5 and Asp7, alternatively. The three resulting chemical structures are:

YIDTNNDGWEGDELLA (DND),
YINTDNDGWEGDELLA (NDD) and
YIDTDNNGWEGDELLA ( $D D N$ ).
These structures are termed DND, NDD and DDN in this section.
The next step was to relax these molecular structures while coordinating a $\mathrm{Ca}^{2+}$ atom (we decided to use $\mathrm{Ca}^{2+}$ instead of a $\mathrm{Ln}^{3+}$ for computational simplicity and to avoid the spin degrees of freedom in the relaxation step). The CaLBT molecular structure was fully optimized using the SIESTA code, until the maximum atomic forces were less than $0.01 \mathrm{eV} / \AA$. A real space grid with an equivalent plane wave cutoff of 200 Ry -enough to ensure convergence- has been used to calculate the various matrix elements. The obtained relaxed structures may be observed in Fig. 5.1.

Figure S5.1. Ball\&stick representation of the relaxed molecular structures of (a) Ca@DND, (b) $C a @ D D N$ and (c) Ca@NDD.

As can be seen in these depictions, the main secondary structure of the polypeptide remains practically unaltered, i.e. it has not been affected by changes on the coordination environment around the lanthanoid. We used these three coordination schemes, which belong to robust structures, to explore the effect of different donor atoms on the ground state description using the SIMPRE computational package. As a first step, we have defined three types of coordination oxygen atoms: (a) those that come from a monocoordinated carboxylate ligand (Asp[3, 5, 7], which has a formal charge of -1.0 ), (b) those arising from a bicoordinated carboxylate ligand (Glu11 \& Glu14, with a formal charge -0.5 ) and (c) those corresponding to formally uncharged oxygens (Trp(9), Asn[3, 5, 7], formal charge 0.0). A similar approach, using formal charges and the original
point charge electrostatic model (PCEM), was implemented to investigate magnetic anisotropy on Dy complexes. ${ }^{14}$ In this work, we improve this strategy by using the Radial Effective Charge (REC) model, which incorporates covalent effects through the radial displacement parameter $\left(D_{r}\right)$ and its corresponding effective charge $\left(Z_{i}\right)$ (See Figure S4.2). ${ }^{15}$

Figure S5.2. Electronic pair of a ligand $X$ oriented towards the nucleus of a trivalent lanthanoid cation. The effective charge is located between the lanthanoid and the donor atom at $R_{\text {eff }}=R_{i}-D_{r}$.

In a first step, we start the qualitative exploration by sampling a few ratios for the parameters $D_{r}$ and $Z_{i}$. Three different sets of REC parameters were defined (see Table 5.3), corresponding to rising estimates of the covalency effect. This allowed us to discriminate and select only robust results, where the connection between peptidic sequence and nature of the ground state is not dependent on our parameter choice. One can observe that the REC parameters of the atoms with formal charge -1.0 are equivalent for all three sets. They have been extracted from previous works where they were successfully used to describe the properties of either oxo atoms from a polyoxometalate ligand ${ }^{16}$ or hydroxy $\left(\mathrm{OH}^{-}\right)$ligands. ${ }^{17}$ In the other two cases -formal charges -0.5 and $0.0-$, we have considered three different possibilities, always keeping constant the total $D_{r} \cdot Z_{i}$ product. ${ }^{18}$ To obtain an approximated order of magnitude, we considered the REC parameters ( $D_{r}=1.1 \AA$ and $Z_{i}=$ 0.085 ) which reproduced the spectroscopic energy levels of a system coordinated by the bidentate ligand oxydiacetate (ODA). ${ }^{19}$ In this latter case, the donor atoms are of similar nature than the ones of our case (carboxylates and carbonyl groups), having an average formal charge of $-2 / 3$.

Table S5.3. Description of the different parameter sets used in the calculations. Each ligand described by its formal charge ( $-1.0,-0.5$ or 0.0 ) has a $D_{r} / Z_{i}$ value correspondence.

| Formal Charge | Mode $\mathbf{1}$ |  | Mode 2 |  | Mode 3 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{D}_{\mathbf{r}}(\mathbf{\AA})$ | $\mathbf{Z i}$ | $\mathbf{D}_{\mathbf{r}}(\mathbf{\AA})$ | $\mathbf{Z}_{\mathbf{i}}$ | $\mathbf{D}_{\mathbf{r}}(\mathbf{\AA})$ | $\mathbf{Z}_{\mathbf{i}}$ |
| -1.0 | 0.895 | 0.105 | 0.895 | 0.105 | 0.895 | 0.105 |

After a first initial sampling using these discrete sets, we decided that a promising control of the qubit behavior could be performed in the $\mathrm{Nd}^{3+}$ derivative, as we find that its ground state can be rationally controlled by specific changes in the peptidic sequences: we obtained that an NDD environment consistently produces a different $M_{J}$ in the ground doublet compared with DND. For the other metals the sampling was either inconclusive or indicated a constant ground doublet independently of the position of the aspartate/arginine residues. Thus, we prepared a new set of continuous calculations with a fine-grained variation of the covalence parameters $\left(D_{r}\right)$. These calculations were performed for both $\mathrm{Nd}^{3+}$ and $\mathrm{Er}^{3+}$, using the latter as an example of a ground doublet that seems unmodified with the structural changes.

Thus we maintained a constant ratio $D_{r} / Z_{i}$ and varied $D_{r}$ between two reasonable limits of covalence. The results obtained from this exhaustive exploration are described in the main text (see Fig. 3).

The REC parameters $D_{r}$ and $Z_{i}$ are obtained using the following equations:

$$
\begin{align*}
& Z_{i}(-1.0)=0.105  \tag{4}\\
& Z_{i}(0.0)=0.065 \cdot 1.0154^{n}  \tag{5}\\
& Z_{i}(-0.5)=0.083 \cdot 1.0085^{n} \tag{6}
\end{align*}
$$

with $n$ variying between 0 and 20, while $D_{r}$ for all cases is obtained for $D_{r} \cdot Z_{i}=0.093$.

## S6 Steps for the design of a low spin-vibrationalcoupling peptidic spin

A major advantage of using peptidic spin qubits as building blocks for spintronics is the possibility for systematic property optimization: whether one is interested in quantum coherence or in any other specific spintronic effect, the rational procedure to improve the desired property would be to perform a screening of a combinatorial peptide library, i.e. to make combinations of substitutions of individual aminoacids in the sequence to obtain progressively better properties.

In this case, we suggest one would proceed as follows:
In a first phase, on would employ an inexpensive approach such as Force Fields (e.g. using the Amber suite) to estimate the molecular vibrations of a given peptidic spin qubit. With a set of normal vibrational modes, it is then possible to generate a set of distorted geometries, following each of these normal modes. One would perform an energy cutoff discarding all vibrational modes above 300 K and thus greatly simplifying the problem, since there is no interest in calculating the high-energy modes which will not be populated at any reasonable temperatures. One would then calculate the energy of the spin qubit, corresponding in our case to the magnetic levels of the ground NdLBT doublet at the operating magnetic field. This can be done inexpensively employing an effective electrostatic approach such as the REC model with SIMPRE or with more care by ab initio methods (MOLCAS or ORCA). As presented recently in Escalera-Moreno et al. ${ }^{20}$ this is enough to determine the set of key local vibrations in the relaxation of a molecular spin qubit (or a single-molecule magnet).

The second phase of the work would involve designing a peptidic library, based on the original peptidic spin qubit. From the first phase one can determine, for the vibrations that are key for spin relaxations, which are the aminoacids with the greatest displacement. Moreover, one can also determine which are the aminoacid-aminoacid distances that are most affected by these key vibrations. Exploring controlled changes in precisely these two sets of aminoacids should guide the design of the peptidic library, which can then be systematically explored. From the point of view of the experiment and to save time, we suggest that it is enough for each peptide to do a relatively inexpensive test by means of an quick EPR experiment, such as determining the presence and intensity of a spin echo at 100 K , which does not require the time- (and resource-) intensive task of cooling the system to liquid He temperatures. This would allow exploring many samples a day.

## S7 Crystallization attempts of the LBT peptide

Crystallography of LBT proved challenging. Peptide crystallization was pursued by the vapor diffusion method using the sitting drop technique by mixing $0.4 \mu \mathrm{l}$ of peptide ( 2.5 and $5 \mathrm{mg} / \mathrm{ml}$ in 10 mM HEPES and $1.2 \mathrm{mM} \mathrm{TbCl}_{3} \mathrm{pH} 7.0$ ) with $0.4 \mu \mathrm{l}$ of different reservoir solutions in 96 -well MRC-type crystallization plates. Reservoir solutions were based on previous reported crystallization conditions ( $3.7 \mathrm{mM} \mathrm{NaCl}, 100 \mathrm{mM}$ Tris at pH 6.5 and $40 \% \mathrm{t}$-butanol) as well as in different sparse matrix screens. ${ }^{2}$ Sparse matrix screens used for peptide crystallization were JBScreen Classic HTS I and II, JBScreen JCSG++ and JBScreen PACT++ from Jena Bioscience (Germany). We tested all resulting crystals at the synchrotrons Alba (Barcelona, Spain) and Diamond Light Source (Didcot, UK), but in every case they corresponded to salts. Thus, we were unable to reproduce the previous reported crystals obtained by the microbatch technique.

Figure S7. (a) Scheme of the typical MRC-type plate we used for crystallization assays. (b) View of a pair of wells with spherulites in one of them from one of our assays.
