January 23, 2019

Abstract

Let $c \in \mathbb{Z}_{>0}^m$, $A \in \mathbb{Z}^{n \times m}$, and $b \in \mathbb{Z}^n$. We show under fairly general conditions that the non-uniform Physarum dynamics

$$\dot{x}_e = a_e(x,t) \left(|q_e| - x_e \right)$$

converges to the optimum solution x^* of the weighted basis pursuit problem minimize $c^T x$ subject to $Af = b$ and $|f| \leq x$. Here, f and x are m-vectors of real variables, q minimizes the energy $\sum_e (c_e/x_e) q_e^2$ subject to the constraints $Aq = b$ and $\mathrm{supp}(q) \subseteq \mathrm{supp}(x)$, and $a_e(x,t) > 0$ is the reactivity of edge e to the difference $|q_e| - x_e$ at time t and in state x. Previously convergence was only shown for the uniform case $a_e(x,t) = 1$ for all e, x, and t.

We also show convergence for the dynamics

$$\dot{x}_e = x_e \cdot \left(g_e \left(\frac{|q_e|}{x_e} \right) - 1 \right),$$

where g_e is an increasing differentiable function with $g_e(1) = 1$. Previously convergence was only shown for the special case of the shortest path problem on a graph consisting of two nodes connected by parallel edges.

1 Introduction

In [BBK+17] and [FCP18] it was shown that the Physarum dynamics (2) can solve the *weighted basis pursuit problem*

$$\text{minimize } c^T x \text{ subject to } Af = b \text{ and } |f| \leq x, \tag{1}$$

where $c \in \mathbb{Z}_{>0}^m$, $A \in \mathbb{Z}^{n \times m}$, $b \in \mathbb{Z}^n$, $n \leq m$, and x and f are an m-vectors of real variables. The absolute-value operator is applied componentwise. A is assumed to have full row-rank. For simplicity, we also assume that any two basic feasible solutions of $Af = b$ have distinct cost[1]; in particular, the optimal solution (f^*, x^*) to (1) is unique. [BBK+17, FCP18] actually shows convergence under the more general condition $c \geq 0$ and $c^T |f| > 0$ for any f in the kernel of A, but we do not need this generality here. We index the rows of A by i and the columns of A by e and, for historical reasons (see Section 2.1), refer to the rows as nodes and the columns as edges.

The Physarum dynamics evolves a vector $x(t) \in \mathbb{R}_{\geq 0}^m$ according to the dynamics

$$\dot{x} = |q| - x, \tag{2}$$

where q is the minimum energy feasible solution according to the resistances $r_e = c_e/x_e$:

$$q = \arg\min_f \left\{ \sum_e (c_e/x_e) f_e^2 : Af = b \text{ and } f_e = 0 \text{ whenever } x_e = 0 \right\}.$$

The Physarum dynamics was introduced by biologists [TKN07] as a model of the behavior of the slime mold Physarum Polycephalum. We discuss the biological background in Section 2.

---

*Max Planck Institute for Informatics, Saarland Informatics Campus

[1] A basic feasible solution of $Af = b$ has the form $f = (f_B, f_{\overline{B}})$, where B is a subset of $[m]$ of size n, $\overline{B} = [m] \setminus B$, the submatrix A_B of A is invertible, $f_B = A_B^{-1} b$, and $f_{\overline{B}} = 0$. The cost of such a solution is $c^T |f|$.

Theorem 1 ([BBK$^+$17, FCP18]). *Assume a strictly positive start vector $x(0) \in R_{>0}^m$. Then the solution $x(t)$ to the dynamics (2) is defined on $[0,\infty)$, $x(t) > 0$ for all t, and $x(t)$ and $|q(t)|$ converge to the optimal solution x^* of (1).*

In this paper, we consider the more general dynamics (3) and (5). In the dynamics (3) the edges react with different speed to differences between minimum energy solution and capacity, i.e.,

$$\dot{x}_e = a_e(x,t)(|q_e| - x_e), \tag{3}$$

where $a_e(x,t) \geq 0$ is the reactivity of edge e at time t, i.e., the edges no longer react uniformly to differences between $|q|$ and x, but the reactivity depends on the edge, the current state, and the time. We refer to (3) as the *nonuniform Physarum dynamics*. The special case that $a_e(x,t)$ is a positive constant for each edge was introduced in [NIU$^+$07] to model the behavior of Physarum Polycephalum in non-uniform environments; see Section 2.2. We show

Theorem 2. *Assume $x(0) > 0$, $0 \leq a_e(x,t) \leq C$ for all e, x, and t and some constant C, and $a_e(x,t)$ is Lipschitz-continuous. Then:*
(a) The dynamics (3) has a unique solution $x(t) > 0$ for $t \in [0,\infty)$.
(b) The function

$$L(x,t) = \sum_e (c_e/x_e)q_e^2 + \sum_e c_e x_e \tag{4}$$

is a Lyapunov function for the dynamics, i.e., $\frac{d}{dt}L(x,t) \leq 0$ for all $t \in [0,\infty)$. Moreover, $\frac{d}{dt}L(x,t) = 0$ if and only if for all e: either $a_e(x,t) = 0$ or $x_e(t) = 0$ or $|q_e| = x_e$.
(c) If, in addition, $a_e(x,t) \geq \varepsilon$ for some positive ε and all e, x, and t, $x \geq 0$ is a fixed point of (3) if and only if $x = |f|$ for a basic feasible solution of $Af = b$.
(d) Under the same additional assumption as in (c), $x(t)$ and $|q(t)|$ converge to a fixed point of (3) as t goes to infinity.
(e) If, in addition, $a_e(x,t)$ does not depend on x and $\frac{d}{dt}a_e(t) \leq 0$ for all e and t, $x(t)$ and $|q(t)|$ converge to x^* as t goes to infinity. In particular, this holds true if $a_e(t)$ is a positive constant for all e.

The proof of part (a) is standard and part (c) was shown in [BBK$^+$17]. The Lyapunov function in part (b) was introduced in [FD$^+$18]. In [FCP18] it was shown to be Lyapunov function for the uniform case ($a_e(x,t) = 1$ for all e, x, and t). Part (d) follows easily from parts (b) and (c). Finally, the proof of part (e) is inspired by by [BBK$^+$17].

The function $L(x,t)$ is a Lyapunov function for the Physarum dynamics under very general conditions. Essentially, the only requirement is that $\dot{x}_e$ has the same sign as $|q_e| - x_e$. For the existence of a solution with domain $[0,\infty)$, we also need that $\dot{x}_e/(|q_e| - x_e)$ is bounded. For the convergence to a fixed point, we need in addition that $\dot{x}_e/(|q_e| - x_e)$ is bounded away from zero.

In the dynamics (5) each edge has its own transfer function that determines how its reacts to the ratio of flow and capacity being larger or smaller than one, i.e.,

$$\dot{x}_e = x_e \cdot \left(g_e\left(\frac{|q_e|}{x_e}\right) - 1 \right) \quad \text{for all } e \in [m], \tag{5}$$

where the response function $g_e : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ is assumed to be an increasing differentiable function satisfying $g_e(1) = 1$. Bonifaci introduces this model in [Bon16] in order to deal with the larger class of response functions proposed in the biological literature. For the shortest path problem in a network of parallel links[2], [Bon16] shows convergence to the shortest path. Bonifaci assumes the same response function for every edge, but his proof actually works for response functions depending on the edge. We show

Theorem 3. *Assume g_e is increasing and differentiable and satisfies $g_e(1) = 1$ for all e.*
(a) The dynamics (5) has a unique solution $x(t) > 0$ for $t \in [0,\infty)$.
(b) $x \geq 0$ is a fixed point of (5) if $x = |f|$ for a basic feasible solution of (1).

---

[2]The shortest path problem is a min-cost flow problem where we want to send one unit of flow between two distinguished nodes. For the case of parallel links, the graph has exactly two nodes and all edges run between these nodes. We have a graph with two nodes and several parallel edges connecting them,
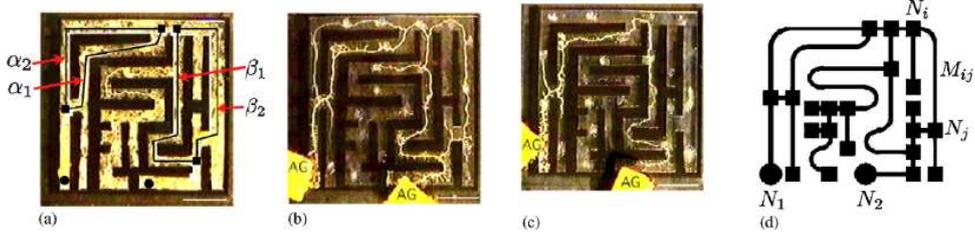

Figure 1: The experiment in [NYT00] (reprinted from there): (a) shows the maze uniformly covered by Physarum; yellow color indicates presence of Physarum. Food (oatmeal) is provided at the locations labeled AG. After a while the mold retracts to the shortest path connecting the food sources as shown in (b) and (c). (d) shows the underlying abstract graph. The video [Vid] shows the experiment.

(c) The function

$$L(x,t) = \sum_e (c_e/x_e)q_e^2 + \sum_e c_e x_e \qquad (6)$$

is a Lyapunov function for the dynamics, i.e., $\frac{d}{dt}L(x,t) \leq 0$ for all $t \in [0,\infty)$. Moreover, $\frac{d}{dt}L(x,t) = 0$ if and only if x is a fixed point.

(d) $x(t)$ and $|q(t)|$ converge to a fixed point of (5).

(e) If, in addition, $g_e(y) \geq 1 + \alpha(y-1)$ for some $\alpha > 0$ and all e and y, $x(t)$ and $|q(t)|$ converge to x^* as t goes to infinity.

The proof of part (a) is standard and part (b) was shown in [BBK+17]. The Lyapunov function in part (c) was introduced in [FD+18]. Part (d) follows easily from part (c). Finally, the proof of part (e) is inspired by by [BBK+17]. The theorem above also holds if the function f_e may depend on time and state.

Nature does not compute exactly, i.e., one should not expect that $\dot{x}_e$ is exactly equal to $|q_e| - x_e$ or to $g_e(|q_e|/x_e) - 1$ in a biological system. Rather, there will be noise. Our results show that the dynamics (3) and (5) are fairly robust against noise, i.e., variations in $a_e(x,t)$ and $f_e(x,t,y)$.

In Section 2, we review the biological background and related work, in Section 3, we prove Theorem 2, and in Section 4, we prove Theorem 3. In Section 5, we state some open problems.

2 Background

2.1 The Shortest Path Experiment

Physarum Polycephalum is a slime mold that apparently is able to solve shortest path problems. Nakagaki, Yamada, and Tóth [NYT00] report about the following experiment; see Figure 1. They built a maze, covered it by pieces of Physarum (the slime can be cut into pieces which will reunite if brought into vicinity), and then fed the slime with oatmeal at two locations. After a few hours the slime retracted to a path following the shortest path in the maze connecting the food sources. The authors report that they repeated the experiment with different mazes; in all experiments, Physarum retracted to the shortest path.

The paper [TKN07] proposes a mathematical model for the behavior of the slime and argues extensively that the model is adequate. Physarum is modeled as an electrical network with time varying resistors. We have a simple *undirected* graph $G = (N, E)$ with two distinguished nodes modeling the food sources. Each edge $e \in E$ has a positive length c_e and a positive capacity $x_e(t)$; c_e is fixed, but $x_e(t)$ is a function of time. The resistance $r_e(t)$ of e is $r_e(t) = c_e/x_e(t)$. In the electrical network defined by these resistances, a current of value is forced 1 from one of the distinguished nodes to the other. For an (arbitrarily oriented) edge $e = (u,v)$, let $q_e(t)$ be the resulting current over e. Then, the capacity of e evolves according to the differential equation

$$\dot{x}_e(t) = |q_e(t)| - x_e(t), \qquad (7)$$

where $\dot{x}_e$ is the derivative of x_e with respect to time. In equilibrium ($\dot{x}_e = 0$ for all e), the flow through any edge is equal to its capacity. In non-equilibrium, the capacity grows (shrinks) if the absolute value of

the flow is larger (smaller) than the capacity. It is well-known that the electrical flow q is the feasible flow minimizing energy dissipation $\sum_e r_e q_e^2$ (Thomson's principle).

2.2 Minimum Risk Paths

In [NIU+07], Nakagaki et. al. study the following scenario, see Figure 2. They cover a rectangular plate with Physarum and feed it at opposite corners of the plate. Two thirds of the plate is put under a bright light, one third is kept in the dark. Under uniform lighting conditions, Physarum would retract to a straight-line path connecting the food sources [NYT00]. However, Physarum does not like light and therefore forms a path with one kink connecting the food sources. The path is such that the part under light is shorter than in a straight-line connection. In the theory section of [NIU+07], the dynamics

$$\dot{x}_e(t) = |q_e| - a_e x_e(t) \tag{8}$$

is proposed. The constant a_e is the *decay rate* of edge e if there is no flow on it. To model the experiment, $a_e = 1$ for edges in the dark part of the plate, and $a_e = C > 1$ for the edges in the lighted area, where C is a constant. [NIU+07] report that in computer simulations, the dynamics (8) converges to the shortest source-sink path with respect to the modified cost function $a_e c_e$.

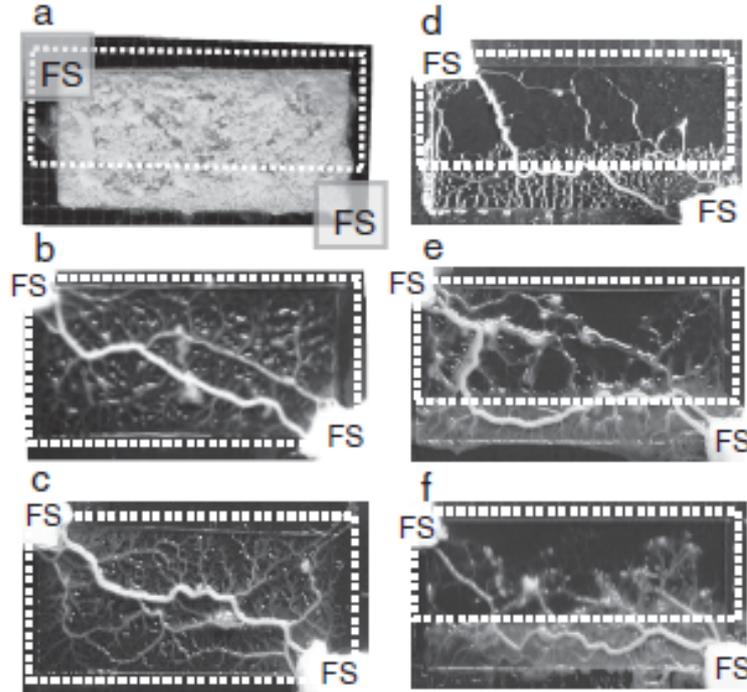

Figure 2: Photographs of the connecting paths between two food sources (FS). (a) The rectangular sheet-like morphology of the organism immediately before the presentation of two FS and illumination of the region indicated by the dashed white lines. (b),(c) Examples of connecting paths in the control experiment in which the field was uniformly illuminated. A thick tube was formed in a straight line (with some deviations) between the FS. (d)-(f) Typical connecting paths in a non-uniformly illuminated field (95 K lx). Path length was reduced in the illuminated field, although the total path length increased. Note that fluctuations in the path are exhibited from experiment to experiment. (Figure and caption reprinted from [NIU+07, Figure 2].)

2.3 A Reformulation: Nonuniform Physarum

Let $y_e = a_e x_e$. The electrical flow q is determined by the resistances $r_e = c_e/x_e$. Therefore, we write $q(r(t))$ instead of $q(t)$ for clarity. Next observe that $r_e = c_e/x_e = (a_e c_e)/(y_e)$. Thus if we take y as the vector of edge capacities and $(a_e c_e)_e$ as the vector of costs, we get the same electrical flow. We can express (8) as a dynamics for y as

$$\dot{y}_e = a_e \dot{x}_e = a_e(|q_e(r_e)| - a_e x_e) = a_e(|q_e(r_e)| - y_e).$$

So we may instead consider the dynamics

$$\dot{y}_e = a_e(|q_e| - y_e)$$

under the modified cost function $a_e c_e$. This is our dynamics (3), where we generalized further by allowing a_e to depend on x and t. In this model, the *quantity a_e indicates the responsiveness (reactivity) of an edge to differences between flow and diameter*.

2.4 Beyond Shortest Paths

The biological experiments concern shortest paths. The papers [BMV12, Bon13] showed Theorem 1 for the shortest path problem and the transportation problem; here A is the node-arc incidence matrix of a directed graph, b is the supply-demand vector of a transportation problem, i.e., $\sum_i b_i = 0$, and $c > 0$ are the edge costs. Convergence for the discretization of (2) was shown in [BBD$^+$13].

The theoretical literature soon asked whether the dynamics (2) can also solve more general problems. The basis pursuit problem was first studied in [SV16a] and convergence of the discretization was shown. Theorem 1 was shown in [BBK$^+$17]. The function (6) was introduced in [FD$^+$18] and shown to be a Lyapunov function for (2) in [FCP18].

The paper [Bon16] introduces and studies the dynamics (5)

The directed version of the Physarum dynamics evolves according do the equation

$$\dot{x}_e = q_e - x_e. \tag{9}$$

No biological significance is claimed for this dynamics. It can solve linear programs with positive cost vectors [IJNT11, SV16b]. In [BBD$^+$13], convergence was claimed for the non-uniform dynamics $\dot{x}_e = a_e(q_e - x_e)$. The proof is incorrect.[3]

3 The Proof of Theorem 2

3.1 Preliminaries

For a capacity vector $x \geq 0$ and a vector $f \in \mathbb{R}^m$ with $\mathrm{supp}(f) \subseteq \mathrm{supp}(x)$, we use $E_x(f) = \sum_e (c_e/x_e) f_e^2$ to denote the *energy* of f. The energy of f is infinite, if $\mathrm{supp}(f) \not\subseteq \mathrm{supp}(x)$. We use $\mathrm{cost}(f) = \sum_e c_e |f_e| = c^T |f|$

---

[3] In the unpublished proof of Lemma 10, the authors argue: We first follow the development in [IJNT11], taking the reactivities into account. From

$$\frac{d}{ds} x_e e^{a_e s} = \dot{x}_e e^{a_e s} + a_e x_e e^{a_e s} = a_e(q_e - x_e)e^{a_e s} + a_e x_e e^{a_e s} = a_e q_e e^{a_e s}$$

we have

$$x_e(t) e^{a_e t} - x_e(0) = \int\limits_{s=0}^{s=t} a_e q_e(s) e^{a_e s} ds$$

and hence

$$x_e(t) = x_e(0)e^{-a_e t} + \int\limits_{s=0}^{s=t} a_e q_e(s) e^{-a_e(t-s)} ds = x_e(0)e^{-a_e t} + (1 - e^{-a_e t}) \int\limits_{s=0}^{s=t} a_e q_e(s) \frac{e^{-a_e(t-s)}}{1 - e^{-a_e t}} ds.$$

Let

$$\bar{q}_e(t) = \int\limits_{s=0}^{s=t} a_e Q_e(s) \frac{e^{-a_e(t-s)}}{1 - e^{-a_e t}} ds.$$

Since $\int_0^t e^{-a_e(t-s)} ds = (1 - e^{-a_e t})/a_e$, $\bar{q}(t)$ is a convex combination of flows and hence a flow. This argument is fallacious. For each edge $\bar{q}_e$ is a convex combination. But these combinations are not uniform over edges. Therefore $\bar{q}$ is NOT a convex combination of flows.

to denote the *cost* of f. Note that $E_x(x) = \sum_e (c_e/x_e)x_e^2 = \sum_e c_e x_e = \text{cost}(x)$.

We use R to denote the diagonal matrix with entries c_e/x_e; here we use the convention that attention is restricted to the edges e with $x_e > 0$. In part (a) of Theorem 2, it is shown that $x(t) > 0$ for all t if $x(0) > 0$. However, in the limit some edges may have capacity zero. Energy-minimizing solutions are induced by node potentials $p \in \mathbb{R}^n$ according to the following equations:

$$b = Aq \tag{10}$$

$$q = R^{-1}A^T p \tag{11}$$

$$AR^{-1}A^T p = b \tag{12}$$

We give a short justification. q minimizes the quadratic function $\sum_e (c_e/x_e)q_e^2$ subject to the constraints $Aq = b$. The KKT conditions state that at the optimum, the gradient of the objective is a linear combination of the gradients of the constraints. Thus

$$2(c_e/x_e)q_e = \sum_i p_i A_{i,e}$$

for some vector $p \in \mathbb{R}^n$. Absorbing the factor 2 into p yields equation (11). Substitution of (11) into (10) gives (12).

We next collect some well-known properties of the minimum energy solution; the proof of part (b) can, for example, be found in [BBK$^+$17]. Let D be the maximum absolute value of a square submatrix of A.

   (i) The minimum energy solution is defined by (12) and (11). It is unique.
   (ii) $|q_e| \leq D\|b\|_1$ for every $e \in [m]$.
   (iii) $E_x(q) = \sum_e (c_e/x_e)q_e^2 = b^T p$, where p is defined by (12). This holds since $E_x(q) = q^T R q = p^T A R^{-1} R R^{-1} A^T p = p^T A R^{-1} A^T p = p^T b$.

With the help of (11), the dynamics can we rewritten as

$$\dot{x}_e = a_e(x,t)\left(\left|\frac{x_e}{c_e}A_e^T p\right| - x_e\right) = a_e(x,t)x_e\left(\frac{|A_e^T p|}{c_e} - 1\right). \tag{13}$$

3.2 Existence

The right-hand side of (3) is locally Lipschitz-continuous in x and t. The function $a_e(x,t)$ is locally Lipschitz by assumption, q is an infinitely often differentiable rational function in the x_e and hence locally Lipschitz. Furthermore, locally Lipschitz-continuous functions are closed under additions and multiplications. Thus $x(t)$ is defined and unique for $t \in [0,t_0)$ for some t_0.

Since $a_e(x,t) \leq C$ for all e, x and t, we have $\dot{x}_e \geq -Cx$ and hence $x_e \geq x_e(0)e^{-Ct}$. Also since $|q_e(t)| \leq D\|b\|_1$ for all e and t, we have $\dot{x}_e \leq C(D\|b\|_1 - x)$ and hence $x_e(t) \leq \max(x_e(0), D\|b\|_1)$ for all t. In particular, the solution is bounded. Thus, $t_0 = \infty$ by well-known results of maximal solutions of ordinary differential equations [Har01, Corollary 3.2].

The condition $a(x,t) \leq C < \infty$ is crucial for existence. Let $n = 0$, $m = 1$ and $a(x,t) = 1/x$. The matrix A is 0×1, i.e., there are no constraints. Then the minimum energy solution is the null-vector of dimension one and (3) becomes $\dot{x} = 1/x \cdot (0 - x) = -1$; the domain of definition is $[0, x(0))$.

3.3 Fixed Points

A point x is a fixed point if $\dot{x} = 0$. In [BBK$^+$17] is was shown that the fixed points of (2) are the vectors $|f|$, where f is a basic feasible solution of (1). This uses the assumption that any two basic feasible solutions have distinct cost. The proof carries over to (3) under the additional assumption that $a_e(x,t) \geq \varepsilon$ for all e, x and t and some positive ε. Under this additional assumption $\dot{x} = 0$ is equivalent to $|q| = x$ for (2) and (3). This section is reprinted from [BBK$^+$17] with minor adaptions. A vector f' is *sign-compatible* with a vector f (of the same dimension) if $f'_e \neq 0$ implies $f'_e f_e > 0$. In particular, $\text{supp}(f') \subseteq \text{supp}(f)$. We use the following corollary of the finite basis theorem for polyhedra.

Lemma 1. *Let f be a feasible solution of (1). Then f is the sum of a convex combination of at most n basic feasible solutions plus a vector in the kernel of A. Moreover, all elements in this representation are sign-compatible with f.*

Proof. We may assume $f \geq 0$. Otherwise, we flip the sign of the appropriate columns of A. Thus, the system $Af = b$, $f \geq 0$ is feasible and f is the sum of a convex combination of at most n basic feasible solutions plus a vector in the kernel of A by the finite basis theorem [Sch03, Corollary 7.1b]. By definition, the elements in this representation are non-negative vectors and hence sign-compatible with f. $\qquad\square$

Lemma 2. *Assume $a_e(x,t) \geq \varepsilon$ for some positive ε and all e, x, and t, and that no two feasible solutions of $Af = b$ have the same cost. If f is a basic feasible solution of (1), then $x = |f|$ is an fixed point. Conversely, if x is an fixed point, then $x = |f|$ for some basic feasible solution f.*

Proof. Let f be a basic feasible solution, let $x = |f|$, and let q be the minimum energy feasible solution with respect to the resistances c_e/x_e. We have $Aq = b$ and $\text{supp}(q) \subseteq \text{supp}(x)$ by definition of q. Since f is a basic feasible solution there is a subset B of size n of the columns of A such that A_B is non-singular and $f = (A_B^{-1}b, 0)$. Since $\text{supp}(q) \subseteq \text{supp}(x) = \text{supp}(f) \subseteq B$, we have $q = (q_B, 0)$ for some vector q_B. Thus, $b = Aq = A_B q_B$ and hence $q_B = f_B$. Therefore $\dot{x} = |q| - x = 0$ and x is an fixed point.

Conversely, if x is an fixed point, $|q_e| = x_e$ for every e. By changing the signs of some columns of A, we may assume $q \geq 0$. Then $q = x$. Since $q_e = (x_e/c_e)A_e^T p$ by (11), we have $c_e = A_e^T p$, whenever $x_e > 0$. By Lemma 1, q is a convex combination of basic feasible solutions plus a vector in the kernel of A that are sign-compatible with q. The vector in the kernel is zero since q is a minimum energy solution[4]. For any basic feasible solution z contributing to q, we have $\text{supp}(z) \subseteq \text{supp}(x)$. Summing over the $e \in \text{supp}(z)$, we obtain $\text{cost}(z) = \sum_{e \in \text{supp}(z)} c_e z_e = \sum_{e \in \text{supp}(z)} z_e A_e^T p = b^T p$, i.e., all basic feasible solutions used to represent q have the same cost. Since we assume the costs of distinct basic feasible solutions to be distinct, q is a basic feasible solution. $\qquad\square$

Corollary 1. *Assume $a_e(x,t) \geq \varepsilon$ for some positive ε and all e, x, and t and that no two feasible solutions of $Af = b$ have the same cost. The set of fixed points is a discrete set.*

3.4 The Lyapunov Function

Lemma 3. *$L(x,t) = p^T b + c^T x$ is a Lyapunov function. More precisely, $\frac{d}{dt}L(x,t) \leq 0$ always with equality only if for all e either $x_e = 0$ or $a_e(x,t) = 0$ or $|A_e^T p| = c_e$.*

Proof. Taking the derivative of (12) with respect to time yields

$$A\frac{d}{dt}(R^{-1})A^T p + AR^{-1}A^T \dot{p} = 0 \tag{14}$$

We next compute the derivative of both summands of $L(x,t)$ with respect to time separately. For the first summand we obtain

$$\frac{d}{dt}p^T b = \frac{d}{dt}p^T AR^{-1}A^T p = \dot{p}^T AR^{-1}A^T p + p^T A\frac{d}{dt}(R^{-1})A^T p + p^T AR^{-1}A^T \dot{p}$$

$$= -p^T A\frac{d}{dt}(R^{-1})A^T p = -\sum_e (A_e^T p)^2 \dot{x}_e/c_e$$

$$= -\sum_e (A_e^T p)^2 \frac{a_e}{c_e}\left(\frac{x_e}{c_e}|A_e^T p| - x_e\right)$$

$$= -\sum_e a_e c_e x_e \left(\frac{|A_e^T p|^3}{c_e^3} - \frac{|A_e^T p|^2}{c_e^2}\right)$$

where the first equality uses (12), the second equality follows from the product rule of differentiation, the third equality follows from 14, the fourth equality is a simple algebraic manipulation, the fifth equality follows from (13), and the last equality is a simple algebraic manipulation.

---

[4]Assume $q = q^1 + q^2$ with $q^1 \geq 0$, $q_2 \geq 0$, $q_2 \neq 0$, and $Aq_2 = 0$. Then $Aq_1 = b$, $\text{supp}(q_1) \subseteq \text{supp}(q) \subseteq \text{supp}(x)$, and $E_x(q_1) < E_x(q)$, a contradiction.

For the second summand, we obtain

$$\frac{d}{dt}c^T x = \sum_e c_e \dot{x}_e = \sum_e a_e c_e \left(\frac{x_e}{c_e} |A_e^T p| - x_e \right) = \sum_e a_e c_e x_e \left(\frac{|A_e^T p|}{c_e} - 1 \right).$$

Combining the two terms and writing λ_e instead of $\frac{|A_e^T p|}{c_e}$, we obtain

$$\frac{d}{dt}L(x,t) = -\sum_e a_e c_e x_e \left(\lambda_e^3 - \lambda_e^2 - \lambda_e + 1 \right).$$

Since

$$\lambda_e^3 - \lambda_e^2 - \lambda_e + 1 = (\lambda_e^2 - 1)(\lambda_e - 1) = (\lambda_e + 1)(\lambda_e - 1)^2$$

and $\lambda_e \geq 0$, we have $\frac{d}{dt}L(x,t) \leq 0$ always. We have equality only if $a_e x_e(\lambda_e - 1) = 0$ for all e, i.e., for all e either $x_e = 0$ or $a_e(x,t) = 0$ or $|A_e^T p| = c_e$. $\qquad \square$

Corollary 2. *Assume further $a_e(x,t) \geq \varepsilon$ for some positive ε and all e, x and t. Then $L(x,t) = 0$ if and only if x is a fixed point.*

Proof. We have $L(x,t) = 0$ if and only if for all e either $x_e = 0$ or $|A_e^T p| = c_e$. The latter condition is equivalent to $|q_e| = x_e/c_e|A_e^T p| = x_e$. Thus $|q| = x$. $\qquad \square$

3.5 Convergence

From now on, we make the addition assumption that $a_e(x,t) \geq \varepsilon$ for some positive ε and all e, x, and t. It then follows from the general theory of dynamical systems that $x(t)$ converges to a fixed point.

Corollary 3 (Generalization of Corollary 3.3. in [Bon13].). *Assume further $a_e(x,t) \geq \varepsilon$ for all e, x and t. As $t \to \infty$, $x(t)$ and $|q(t)|$ approach a fixed point x_0. Moreover, $E_x(q)$ and $\mathrm{cost}(x)$ converge to $c^T x_0$.*

Proof. The proof in [Bon13] carries over. We include it for completeness. The existence of a Lyapunov function L implies by [LaS76, Corollary 2.6.5] that $x(t)$ approaches the set $\{x \in \mathbb{R}_{\geq 0}^m : \dot{L} = 0\}$, which by Corollary 2 is the same as the set $\{x \in \mathbb{R}_{\geq 0}^m : \dot{x} = 0\}$. Since this set consists of isolated points (Lemma 2), $x(t)$ must approach one of those points, say the point x_0. When $x = x_0$, one has $E_x(q) = E_x(x) = \mathrm{cost}(x) = c^T x$. $\qquad \square$

The assumption $a_e(x,t) \geq \varepsilon > 0$ is crucial as the following example shows. Let $n = m = 1$, consider the task of minimizing $|x|$ subject to the constraint $x = 1$, and let $a(x,t) = e^{-t}/2$ and $x(0) = 1/2$. Then $\dot{x} = \frac{e^{-t}}{2}(1-x)$. Integrating from 0 to t and observing that $x(t) \geq 1/2$ for all t, we obtain

$$x(t) = x(0) + \int_0^t (e^{-s}/2)(1-x(s))ds \leq \frac{1}{2} + \frac{1}{4}\int_0^t e^{-s}ds \leq \frac{1}{2} + \frac{1}{4}(1 - e^{-t}) \leq \frac{3}{4}$$

and hence the dynamics does not converge to the optimal solution $x^* = 1$, which, in this case, is the only fixed point.

It remains to exclude that $x(t)$ converges to a non-optimal fixed point. We can do so under an additional assumption on $a(x,t)$.

Theorem 4. *Assume further that $a_e(x,t)$ does not depend on x, i.e., $a_e(x,t) = a_e(t)$, $a_e(t) \geq \varepsilon$ for some positive ε for all e and t, and $\dot{a}_e(t) \geq 0$ for all e and t. As $t \to \infty$, $x(t)$ converges to the optimal solution x^*.*

Proof. Assume that $x(t)$ converges to a non-optimal fixed point z. Let x^* be the optimal solution, let B be such that $x_e(t) \leq B$ for all e and t (by Section 3.2 the solution is bounded), and let $W = \sum_e x_e^* c_e/a_e \ln(x_e/B)$. Let $\delta = (\mathrm{cost}(z) - \mathrm{cost}(x^*))/2$. Note that for all sufficiently large t, we have $E_x(q(t)) \geq \mathrm{cost}(z) - \delta \geq \mathrm{cost}(x^*) + \delta$. Further, by definition $q_e = (x_e/c_e)A_e^T p$ and thus

$$\dot{W} = \sum_e x_e^* c_e \frac{|q_e| - x_e}{x_e} + \sum_e x_e^* c_e \left(\frac{-\dot{a}_e}{a_e^2} \right) \ln(x_e/B) \geq \sum_e x_e^* |A_e^T p| - \mathrm{cost}(x^*) \geq \sum_e x_e^* A_e^T p - \mathrm{cost}(x^*) \geq \delta,$$

where the first inequality follows from $\ln(x_e/B) \leq 0$ and $\dot{a}_e \geq 0$ and the second inequality follows from $\sum_e x_e^* A_e^T p = b^T p = E_x(q) \geq \mathrm{cost}(x^*) + \delta$. Hence $W \to \infty$, a contradiction to the fact that x is bounded. $\qquad \square$

4 Bonifaci's Refined Model

Bonifaci [Bon16] investigates the dynamics

$$\dot{x}_e = x_e \left(g_e \left(\frac{|q_e|}{x_e} \right) - 1 \right) \quad \text{for all } e \in [m],$$

where the response function $g_e : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ is assumed to be an increasing differentiable function satisfying $g_e(1) = 1$. For the shortest path problem in a network of parallel links, Bonifaci shows convergence to the shortest path. Bonifaci assumes the same response function for every edge, but his proof actually works for response functions depending on the edge. Concrete response functions of this type had been considered earlier in the literature:

- Non-saturating response: $g(y) = y^\mu$ for some $\mu > 0$.

- Saturating response: $g(y) = (1 + \alpha)y^\mu / (1 + \alpha y^\mu)$ for some $\mu, \alpha > 0$.

Lemma 4. $L(x,t) = p^T b + c^T x$ *is a Lyapunov function for the dynamics (5). Moreover $L(x,t) = 0$ if and only if x is a fixed point of (5).*

Proof. We proceed as in the proof of Lemma 3.

$$\begin{aligned}
\frac{d}{dt} L(x,t) &= \frac{d}{dt} \left(p^T b + c^T x \right) \\
&= -\sum_e \left((A_e^T p)^2 \dot{x}_e / c_e - c_e \dot{x}_e \right) \\
&= -\sum_e \left(c_e x_e \frac{(A_e^T p)^2}{c_e^2} \left(g_e \left(\frac{|q_e|}{x_e} \right) - 1 \right) - c_e x_e \left(g_e \left(\frac{|q_e|}{x_e} \right) - 1 \right) \right) \\
&= -\sum_e \left(c_e x_e \left(\frac{|A_e^T p|^2}{c_e^2} - 1 \right) \cdot \left(g_e \left(\frac{|A_e^T p|}{c_e} \right) - 1 \right) \right) \\
&\leq 0,
\end{aligned}$$

since the signs of $(A_e^T p)^2 / c_e^2 - 1$ and $g_e(|A_e^T p|/c_e) - 1$ agree. Note that $g_e(1) = 1$ and g_e is increasing.

Moreover, the derivative is zero if and only if for all e, either $x_e = 0$ or $|A_e^T p| = c_e$. Finally note that for e with $x_e \neq 0$, $|A_e^T p| = c_e$ is equivalent to $|q_e| = x_e$ which in turn is equivalent to $\dot{x} = 0$. $\square$

We remark that the proof above would even work for transfer-functions $g_e(x,t,y)$. It is only important that $g_e(x,t,1) = 1$ and that the function is increasing in y.

It now follows from the general theory of dynamical systems that $x(t)$ converges to a fixed point.

Corollary 4 (Generalization of Corollary 3.3. in [Bon13].)**.** *As $t \to \infty$, $x(t)$ and $|q|(t)$ approach a fixed point x_0. Moreover, $E_x(q)$ and $\mathrm{cost}(x)$ converge to $c^T x_0$.*

Proof. Same proof as Corollary 3. $\square$

We finally show convergence to the optimum solution of (1) under the additional assumption that $g_e(y) \geq 1 + \alpha(y - 1)$ for some $\alpha > 0$ and all y and e.

Theorem 5. *Assume further that $g_e(y) \geq 1 + \alpha(y - 1)$ for some $\alpha > 0$ and all e and y. As $t \to \infty$, $x(t)$ converges to the optimal solution x^*.*

Proof. Assume that $x(t)$ converges to a non-optimal fixed point z. Let x^* be the optimal solution and let $W = \sum_e x_e^* c_e \ln x_e$. Let $\delta = (\mathrm{cost}(z) - \mathrm{cost}(x^*))/2$. Note that for all sufficiently large t, we have $E_x(q(t)) \geq \mathrm{cost}(z) - \delta \geq \mathrm{cost}(x^*) + \delta$. Further, by definition $q_e = (x_e/c_e)A_e^T p$ and thus

$$\begin{aligned}
\dot{W} &= \sum_e x_e^* c_e \frac{x_e \left(g_e \left(\frac{|q_e|}{x_e} \right) - 1 \right)}{x_e} \geq \sum_e x_e^* c_e \alpha \left(\frac{|A_e^T p|}{c_e} - 1 \right) \\
&\geq \alpha \cdot \left(\sum_e x_e^* |A_e^T p| - \mathrm{cost}(x^*) \right) \geq \alpha \cdot \left(\sum_e x_e^* A_e^T p - \mathrm{cost}(x^*) \right) \geq \alpha \cdot \delta,
\end{aligned}$$

9

where the first inequality follows from $f(y) \geq 1 + \alpha(y-1)$ for all y and the last inequality follows from $\sum_e x_e^* A_e^T p = b^T p = E_x(q) \geq \text{cost}(x^*) + \delta$. Hence $W \to \infty$, a contradiction to the fact that x is bounded. $\square$

Convex increasing functions satisfy $g(y) \geq g(1) + \alpha(y-1)$ with $\alpha = g'(1)$.

5 Open Problems

We showed convergence to the optimal solution under the assumption that $a_e(x,t)$ is bounded and bounded away from zero, that $a_e(x,t) = a_e(t)$ does not depend on x, and $\dot{a}_e \geq 0$ always. We argued that the first two assumptions are necessary. How about the other assumptions?

For the uniform dynamics, convergence of a suitable Euler discretization was shown in [BBD$^+$13, SV16a] for the shortest path problem and the basis pursuit problem respectively. What can be said about the convergence of the discretization of the non-uniform dynamics?

There is also the directed dynamics $\dot{x} = q - x$ considered in [IJNT11, SV16b]. Can convergence be shown for the non-uniform version of it?

Our proof that Bonifaci's refined model converges to the optimum requires the additional assumption that $g_e(y) \geq 1 + \alpha(y-1)$ for some $\alpha > 0$ and all e and $y \geq 0$. Can this condition be relaxed?
