

On \mathcal{D} -modules related to the b -function and Hamiltonian flow

Thomas Bitoun and Travis Schedler

ABSTRACT

Let f be a quasi-homogeneous polynomial with an isolated singularity in \mathbf{C}^n . We compute the length of the \mathcal{D} -modules $\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$ generated by complex powers of f in terms of the Hodge filtration on the top cohomology of the Milnor fiber. When $\lambda = -1$ we obtain one more than the reduced genus of the singularity ($\dim H^{n-2}(Z, \mathcal{O}_Z)$ for Z the exceptional fiber of a resolution of singularities). We conjecture that this holds without the quasi-homogeneous assumption. We also deduce that the quotient $\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$ is nonzero when λ is a root of the b -function of f (which Saito recently showed fails to hold in the inhomogeneous case). We obtain these results by comparing these \mathcal{D} -modules to those defined by Etingof and the second author which represent invariants under Hamiltonian flow.

1. Introduction

1.1 Length of $\mathcal{D}[\frac{1}{f}]$ and local cohomology

Throughout the paper, R will denote the ring of complex polynomials in $n \geq 3$ variables and \mathcal{D} the ring of complex polynomial differential operators in n variables. For $f \in R$, we consider the left \mathcal{D} -modules R and $R[\frac{1}{f}]$.

In this paper we compute the length of the left \mathcal{D} -submodule of $R[\frac{1}{f}]$ generated by $\frac{1}{f}$ for f a quasi-homogeneous polynomial with an isolated singularity. We denote this module by $\mathcal{D}[\frac{1}{f}]$. Actually it turns out to be more natural to work with the quotient $R[\frac{1}{f}]/R$, which is the first local cohomology group $H_f^1(R)$, and its left \mathcal{D} -submodule generated by the class of $\frac{1}{f}$, i.e. $\mathcal{D}[\frac{1}{f}]/R$. As R is simple, its length is precisely one less.

Let us state our main result, Theorem 2.1, whose proof is in Section 2, in the case of f a homogeneous polynomial with an isolated singularity, i.e., the zero-locus of f is the cone over a smooth projective variety Y of dimension $n - 2$.

THEOREM 1.1. The length of the left \mathcal{D} -submodule of $H_f^1(R)$ generated by the class of $\frac{1}{f}$ is $1 + \dim H^{n-2}(Y, \mathcal{O}_Y)$.

REMARK 1.2. As an application, we can obtain a necessary and sufficient condition for the left \mathcal{D} -module $R[\frac{1}{f}]$ to be generated by $\frac{1}{f}$. It is well known that $R[\frac{1}{f}]$ is generated by $\frac{1}{f}$ if and only if

Keywords: Hamiltonian flow, Milnor number, \mathcal{D} -modules, Poisson homology, Poisson varieties, Bernstein-Sato polynomial, b -function, local cohomology, nearby cycles, Hodge filtration, Milnor fiber, genus, isolated hypersurface singularities

The first author was supported by EPSRC grant EP/L005190/1. The second author was partly supported by US National Science Foundation Grant DMS-1406553, and is grateful to the Max Planck Institute for Mathematics in Bonn for excellent working conditions.

the Bernstein-Sato polynomial of f has no other integral root than -1 . Indeed for λ the lowest integral root, $\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1} \neq 0$ by [Kas77, Proposition 6.2]. On the other hand, in the case of the theorem the length of $R[\frac{1}{f}]/R = H_f^1(R)$ is $1 + \dim H^{n-2}(X^\circ, \mathbf{C})$, where $X^\circ = \{f = 0\} \setminus \{0\}$ is the punctured cone over Y , as follows from Lemmas 2.3 and 3.5, via Verdier duality. Note that $H^{n-2}(X^\circ, \mathbf{C})$ identifies with the space of primitive cohomology classes of Y in degree $n-2$. Therefore the theorem implies that $H_f^1(R)$, and hence $R[\frac{1}{f}]$, is generated by $\frac{1}{f}$ if and only if the space of primitive cohomology classes of Y in degree $n-2$ equals $H^{n-2}(Y, \mathcal{O}_Y)$ (by the Hodge decomposition, the latter is always a summand of the former, so the statement is that this summand is everything).

EXAMPLE 1.3. When $n = 3$, Y is a smooth curve of genus $g = \dim H^1(Y, \mathcal{O}_Y)$. In this case $\dim H^1(X^\circ, \mathbf{C}) = \dim H^1(Y, \mathbf{C}) = 2g$ so that the length of $H_f^1(R)$ is $1 + 2g$. On the other hand, by the theorem the length of the submodule generated by $\frac{1}{f}$ is only $1 + g$.

In the case of a general f with an isolated singularity, the genus generalizes as follows.

DEFINITION 1.4. Let X be a variety with an isolated singularity at $x \in X$. Let $\rho: \tilde{X} \rightarrow X$ be a resolution of singularities and $Y := \rho^{-1}(x)$. The reduced genus g_x of the singularity x is defined as $\dim H^{n-2}(Y, \mathcal{O}_Y)$.

The reduced genus is independent of the choice of resolution since the derived pushforward $R\rho_*\mathcal{O}_{\tilde{X}}$ is independent of the choice of resolution (any two resolutions can be dominated by a third one, and for a resolution of a smooth variety this pushforward is underived). Then, one can show that $H^{n-2}(Y, \mathcal{O}_Y)$ is the fiber at $x \in X = \text{Spec } R^0\rho_*\mathcal{O}_{\tilde{X}}$ of $R^{n-2}\rho_*\mathcal{O}_{\tilde{X}}$ (since $H^{>n-2}(Y, \mathcal{O}_Y) = 0$).

REMARK 1.5. If f is homogeneous with an isolated singularity at the origin, then g_0 is equal to $\dim H^{n-2}(Y', \mathcal{O}_{Y'})$, where the zero-locus of f is the cone over a smooth projective variety Y' of dimension $n-2$. Indeed Y' is the exceptional fiber of the blow-up of the origin.

REMARK 1.6. We call the dimension of the fiber $H^{n-2}(Y, \mathcal{O}_Y)$ of $R^{n-2}\rho_*\mathcal{O}_{\tilde{X}}$ at x the reduced genus, in contrast to the geometric genus, which is the dimension of the entire stalk of $R^{n-2}\rho_*\mathcal{O}_{\tilde{X}}$ at x , i.e., $\dim H^{n-2}(\rho^{-1}(U), \mathcal{O}_{\rho^{-1}(U)})$ for U a small ball around x . Already when X is the cone over a smooth projective plane curve Y of degree $d \geq 4$, the geometric genus exceeds the reduced genus, with the former $\frac{d(d-1)(d-2)}{6}$ and the latter $\frac{(d-1)(d-2)}{2}$ (the genus of Y).

Our theorem is a particular case of the following conjecture:

CONJECTURE 1.7. Let f be an irreducible complex polynomial with a unique singularity x . The length of the left \mathcal{D} -submodule of $H_f^1(R)$ generated by $\frac{1}{f}$ is $1 + g_x$.

Supporting evidence for Conjecture 1.7 We now would like to list some supporting evidence for the conjecture.

- (i) We prove the conjecture in the case f is quasi-homogeneous, which is one of the main results of this article (Theorem 2.1). This generalizes Theorem 1.1.
- (ii) There is the following analogous result in positive characteristic, which motivated the project:

Suppose that f is a polynomial in n variables with rational coefficients and an isolated singularity at the point 0. Let $\tilde{X} \xrightarrow{\rho} X_0$ be a resolution of the local singularity, of exceptional

fiber Y , as above. Consider further a prime number p large enough so that the denominators of the coefficients of f are prime to p and the reduction modulo p of ρ is a well-defined resolution $\tilde{X}_p \xrightarrow{\rho_p} (X_0)_p$ of the local singularity $(X_0)_p$. Denote by $\tilde{X}_{\bar{p}} \xrightarrow{\rho_{\bar{p}}} (X_0)_{\bar{p}}$ the base-change of ρ_p to an algebraic closure k of \mathbb{F}_p and let $Y_{\bar{p}}$ be its exceptional fiber. Then $H^{n-2}(Y_{\bar{p}}, \mathcal{O}_{Y_{\bar{p}}})$ has a natural Frobenius action and hence is a left $k[F]$ -module. Here is the relevant genus:

DEFINITION 1.8. – Let V be a $k[F]$ -module. The stable part V_s of V is $\cap_{r \geq 1} F^r(V)$.
 – The p -genus g'_p is the dimension of the stable part of $H^{n-2}(Y_{\bar{p}}, \mathcal{O}_{Y_{\bar{p}}})$.

Let R_p be the ring of k -polynomials in n variables, \mathcal{D}_p be the ring of Grothendieck differential operators on the affine space \mathbb{A}_k^n and f_p be the reduction of f modulo p . We have the following result of the first author, see [Bit18]:

THEOREM 1.9. Let f be an absolutely irreducible polynomial in $n \geq 3$ variables with rational coefficients. Suppose that f has a unique singularity. Then for all primes p large enough, the length of the left \mathcal{D}_p -module $H_{f_p}^1(R_p)$ is $1 + g'_p$.

REMARK 1.10. By [AMBL05, Theorem 1.1] the left \mathcal{D}_p -module $H_{f_p}^1(R_p)$ is generated by the class of $\frac{1}{f_p}$. So in fact by Theorem 1.9, for p large enough the length of the left \mathcal{D}_p -submodule generated by the class of $\frac{1}{f_p}$ is $1 + g'_p$.

REMARK 1.11. It is expected, at least in the smooth and connected case, that for infinitely many primes F acts bijectively on $H^{n-2}(Y_{\bar{p}}, \mathcal{O}_{Y_{\bar{p}}})$, see [MS11, Conjecture 1.1]. Thus for infinitely many primes one would have $g'_p = g_0$. Hence for infinitely many primes the length of $H_{f_p}^1(R_p)$ would equal the length of the \mathcal{D} -submodule of $H_f^1(R)$ generated by $\frac{1}{f}$.

- (iii) Another piece of evidence for our conjecture comes from certain \mathcal{D} -modules which control invariants under the Hamiltonian flow, see Subsection 1.3. We show that the corresponding left \mathcal{D} -modules surject to $\mathcal{D}^{\frac{1}{f}}/R$. As a consequence we prove that the above conjecture is equivalent to [ES14, Conjecture 3.8]. In fact this is how we prove the conjecture in the quasi-homogeneous case, since by [ES14, Proposition 3.11] the aforementioned conjecture holds in this case.
- (iv) As an additional piece of evidence for the conjecture, we briefly consider a simple example which is not quasi-homogeneous:

EXAMPLE 1.12. Let X be one of the $T_{p,q,r}$ singularities at the origin in \mathbf{A}^3 , namely $f = x^p + y^q + z^r + xyz$ where $p^{-1} + q^{-1} + r^{-1} < 1$. By [Yan78, Example 4.13], the only integral root of the b -function in this case is -1 . This implies that $H_f^1(R)$ is generated by $\frac{1}{f}$ as a \mathcal{D} -module. So here the conjecture reduces to: using the notation of Definition 1.4, the length of $H_f^1(R)$ is one more than $\dim H^1(Y, \mathcal{O}_Y)$. For a general isolated singularity in \mathbf{A}^n , the length of the former is $1 + \dim H^{n-2}(V \setminus \{0\}, \mathbf{C})$ (by Lemmas 2.3 and the Verdier dual statement of 3.5), where V is a contractible neighborhood of the singularity $\{0\}$, so in our case we reduce to showing that $\dim H^1(V \setminus \{0\}, \mathbf{C}) = \dim H^1(Y, \mathcal{O}_Y)$. For a general isolated singularity in \mathbf{A}^3 , $\dim H^1(V \setminus \{0\}, \mathbf{C}) = 2g + b$, by [Dim04, II.(3.4)], where g is the sum of the genera of the components of \tilde{X} and b is the first Betti number of the dual graph of \tilde{X} . On the other hand, $\dim H^1(Y, \mathcal{O}_Y) = g + b$. So the two are equal exactly when $g = 0$. This is the case for $T_{p,q,r}$ by [Dim04, II.(4.5)]. Hence we conclude that the conjecture holds for the $T_{p,q,r}$ singularities.

Note that, by the above, a special case of the conjecture is the following statement: When $n = 3$ and f has an isolated singularity, then -1 is the only integral root of the b -function

(i.e., $H_f^1(R)$ is generated over \mathcal{D} by $\frac{1}{f}$) if and only if the genera of the components of a resolution \tilde{X} of $X = \{f = 0\}$ are all zero.

REMARK 1.13. We can relax the assumptions of the conjecture. Namely, assume only that f is a polynomial with isolated singularities (not necessarily irreducible). Since $n \geq 3$, the hypersurface $X = \{f = 0\}$ is normal, so its irreducible components equal its connected components. By localization, the conjecture easily implies that the length of the left \mathcal{D} -submodule of $H_f^1(R)$ generated by $\frac{1}{f}$ is then equal to the number of components of X plus the sum of the reduced genera of the isolated singularities.

REMARK 1.14. The conjecture as well as the results of this article also extend to the case $n = 2$, provided we replace the reduced genus by $\dim H^0(Y, \mathcal{O}_Y)/\mathbf{C}$ and the cohomology $H^0(X^\circ, \mathbf{C})$ by the reduced cohomology $H^0(X^\circ, \mathbf{C})/\mathbf{C}$.

1.2 \mathcal{D} -modules related to the b -function

Next, we consider our problem for the variant of $\mathcal{D}\frac{1}{f}$ where $\frac{1}{f}$ is replaced by f^λ for an arbitrary complex number λ . We are interested in the length of the \mathcal{D} -module $\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$.

Let us recall the definition. First of all, the variant of the $\mathcal{D}[\frac{1}{f}]$ -module $R[\frac{1}{f}]$ is the $\mathcal{D}[\frac{1}{f}]$ -module $R[\frac{1}{f}]f^\lambda$. That is the trivial line bundle on $\text{Spec}(R[\frac{1}{f}])$ with generator f^λ , on which a derivation ∂ acts by $\partial \cdot f^\lambda = \lambda\partial(f)f^{-1}f^\lambda$.

DEFINITION 1.15. The left \mathcal{D} -module $\mathcal{D}f^\lambda$ is the left \mathcal{D} -submodule of $R[\frac{1}{f}]f^\lambda$ generated by f^λ , and $\mathcal{D}f^{\lambda+1}$ is the left \mathcal{D} -submodule generated by $f \cdot f^\lambda$.

This definition is reminiscent of that of the b -function of f . Namely the b -function is the minimal polynomial of the action of s on the left $\mathcal{D}[s]$ -module $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$, where s is a variable commuting with \mathcal{D} . More precisely, we consider $\mathcal{D}[\frac{1}{f}][s]f^s$, the free $R[\frac{1}{f}][s]$ -module of rank one with generator f^s , on which derivations ∂ in \mathcal{D} act by $\partial \cdot f^s = s\partial(f)f^{-1}f^s$.

DEFINITION 1.16. The left $\mathcal{D}[s]$ -modules $\mathcal{D}[s]f^s$ and $\mathcal{D}[s]f^{s+1}$ are the left $\mathcal{D}[s]$ -submodules of $\mathcal{D}[\frac{1}{f}][s]f^s$ generated by f^s and $f \cdot f^s$, respectively.

From the definitions it is clear that there is a surjection

$$\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1} \xrightarrow{p_\lambda} \mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1},$$

sending s to λ and f^s to f^λ . Thus the quotient $\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$ certainly vanishes if λ is not a root of the b -function of f . One may wonder about the converse, namely:

QUESTION 1.17. Suppose that λ is a root of the b -function of f . Is the quotient $\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$ nontrivial?

In this paper we compute the length of $\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$ when f is quasi-homogeneous with an isolated singularity. As a consequence we answer Question 1.17 affirmatively in this case.

REMARK 1.18. Note, on the other hand, that Saito shows in [Sai15, Example 4.2] that for all sufficiently small $\epsilon > 0$ and for $f = x^{14} + y^{14} - x^6y^6 + z^5 - \epsilon x^9y^2z$, $\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$ vanishes at $\lambda = -\frac{13}{30}$ even though $-\frac{13}{30}$ is a root of the b -function of f . Thus the answer to Question 1.17 is negative in general, even for an isolated singularity.

Let $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}|_{s=\lambda} := \mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1} \otimes_{\mathbb{C}[s]} \mathbb{C}[s]/(s-\lambda)$ be the restriction to $s = \lambda$. Our result is the following:

THEOREM 1.19. Let f be a complex polynomial in $n \geq 3$ variables, $\lambda \in \mathbb{C}$ and let

$$\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}|_{s=\lambda} \xrightarrow{q_\lambda} \mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$$

be the canonical surjective morphism. Suppose that f is quasi-homogeneous with an isolated singularity at 0.

- (i) If $\lambda \neq -1$, then the canonical morphism q_λ is an isomorphism.
- (ii) If $\lambda = -1$, then the kernel of q_λ is isomorphic to $\delta_0^{\dim H^{n-2}(X^\circ, \mathbb{C})-g_0}$, where δ_0 is the irreducible \mathcal{D} -module supported at 0 and X° is the zero-locus of f minus its singularity.

For $\lambda \neq -1$, the length of $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}|_{s=\lambda}$ was computed in [Kas03, §6.4]. To express the answer we need some notation. Since f is quasi-homogeneous, we may and do endow the polynomial algebra $R = \mathbb{C}[x_1, \dots, x_n]$ with a nonnegative grading such that x_i is homogeneous of degree $m_i \geq 1$ for all i , and f is a homogeneous element of R . We denote the degree of a homogeneous element g of R by $|g|$. Let $J := R/(\frac{\partial f}{\partial x_1}, \dots, \frac{\partial f}{\partial x_n})$ be the Jacobi ring, which has finite complex dimension equal to the Milnor number μ of the isolated singularity. The grading on R induces a grading on the Jacobi ring and the above length is equal to the dimension of a certain homogeneous component. Using the isomorphism of Theorem 1.19, we have:

COROLLARY 1.20. If $\lambda \neq -1$, then the length of $\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$ is $\dim_{\mathbb{C}} J_{-|f|_{\lambda-\sum_i m_i}}$.

REMARK 1.21. Note that, since f is quasi-homogeneous, s acts semisimply on $(s+1)\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$, so in the case $\lambda \neq -1$, the restriction $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}|_{s=\lambda}$ in the theorem can be identified with the generalized eigenspace of $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ under s of eigenvalue λ . This is not true for $\lambda = -1$, since s does not act semisimply on $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ itself in general. The advantage of using generalized eigenspaces is that it gives a direct sum decomposition of $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$. See Remark 1.32 for more details on the summands.

REMARK 1.22. The dimensions in Corollary 1.20 are of a Hodge-theoretic nature, see Theorem 1.34 below.

REMARK 1.23. It would be nice to generalize Conjecture 1.7 to the length of $\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$, for at least some roots λ of the b -function.

1.3 \mathcal{D} -modules related to Hamiltonian flow

Our main technique of proof is to compare the various \mathcal{D} -modules above with certain modules attached to the Hamiltonian flow.

Let us first say a few words about \mathcal{D} -modules on singular varieties. Recall, following Kashiwara, that if X is a singular affine variety equipped with an embedding $X \rightarrow Y$ into a smooth affine variety, one can define the category of “ \mathcal{D} -modules on X ” to be the category of right \mathcal{D}_Y -modules set-theoretically supported on X . This category does not depend on the choice of embedding up to canonical equivalence. It is *not* in general equivalent to the (full) category of modules over any ring. In order to avoid conflict with our distinct notation $\mathcal{D} = \mathcal{D}(\mathbf{A}^n)$ for the ring of polynomial differential operators in n variables, we will use the roman font “ \mathcal{D} -modules” when referring to this category.

We consider the functor $\Gamma_{\mathcal{D}}(X, -)$ from the category of \mathcal{D} -modules on X to vector spaces, given by taking the global sections scheme-theoretically supported on X . This functor does not

depend on the choice of embedding up to canonical isomorphism. Moreover, for every D-module M on X , there is a canonical action on $\Gamma_{\mathcal{D}}(X, M)$ of the Lie algebra of global vector fields on X , coming from the action on M of vector fields on Y , which again does not depend on the choice of embedding.

Let \mathfrak{g} be a Lie algebra and suppose that X is a singular affine variety equipped with an action $\theta : \mathfrak{g} \rightarrow T_X$. The D-module on X we are interested in is the module $M(X, \theta)$ representing the functor of \mathfrak{g} -invariant global sections. Namely, this D-module is such that, for any D-module N on X , we have a functorial isomorphism $\mathrm{Hom}(M(X, \theta), N) \cong \Gamma_{\mathcal{D}}(X, N)^{\mathfrak{g}}$. The D-module $M(X, \theta)$ can be described explicitly as follows.

Let $X \rightarrow Y$ be a closed embedding of X into a smooth affine variety Y with ideal I_X . There is a standard D-module D_X on X , which corresponds to the right \mathcal{D}_Y -module $I_X \mathcal{D}_Y \setminus \mathcal{D}_Y$ supported on X . This does not depend on the choice of the embedding $X \rightarrow Y$ via Kashiwara's equivalence. Moreover, *left* multiplication in \mathcal{D}_Y induces an action on D_X of the vector fields on X by D-module endomorphisms; via θ we obtain an action of \mathfrak{g} . Neither D_X nor the above actions depend on the choice of embedding. The D-module $M(X, \theta)$ on X representing the invariants under the Hamiltonian flow is then $\mathfrak{g} \cdot D_X \setminus D_X$.

We now recall from [ES12, §3.4] the example of interest to us. Let f be a complex polynomial in $n \geq 3$ variables and $X := \{f = 0\} \subseteq \mathbf{A}^n = Y$. To every differential form α of degree $(n-3)$ on \mathbf{A}^n , we associate the vector field $\xi_\alpha := (\partial_1 \wedge \cdots \wedge \partial_n)(d\alpha \wedge df)$. It is parallel to X , i.e. $\xi_\alpha(f) = 0$, and therefore defines a vector field $\xi_\alpha|_X$ on X .

DEFINITION 1.24. The Lie algebra $\mathfrak{g}(f)$ is the vector space $\Omega^{n-3}(\mathbf{A}^n)$ of $(n-3)$ -forms on \mathbf{A}^n , endowed with the Lie bracket

$$\{\alpha, \beta\} := L_{\xi_\alpha}(\beta),$$

for all $\alpha, \beta \in \Omega^{n-3}(\mathbf{A}^n)$, with L_ξ the Lie derivative. We define the Lie homomorphism $\theta : \mathfrak{g}(f) \rightarrow T_X$ by $\theta(\alpha) = \xi_\alpha|_X$, for all $\alpha \in \Omega^{n-3}(\mathbf{A}^n)$.

Note that we also have a Lie homomorphism $\tilde{\theta} : \mathfrak{g}(f) \rightarrow T_{\mathbf{A}^n}$ defined by $\tilde{\theta}(\alpha) = \xi_\alpha$, for all $(n-3)$ -forms α on \mathbf{A}^n .

We then form the D-module $M(X, \theta)$ on X . Let us explicitly write the corresponding left D-module (on \mathbf{A}^n).

DEFINITION 1.25. Let $i_* M(X, \theta)$ be the right D-module on \mathbf{A}^n corresponding to $M(X, \theta)$. We define $M(f)$ to be the left D-module on \mathbf{A}^n obtained by applying to $i_* M(X, \theta)$ the standard equivalence between right and left D-modules on \mathbf{A}^n .

It follows directly from the definitions that

$$M(f) = \mathcal{D}/(\mathcal{D}f + \mathcal{D}\tilde{\theta}(\Omega^{n-3}(\mathbf{A}^n))). \quad (1.26)$$

This left $\mathcal{D}_{\mathbf{A}^n}$ -module represents the functor of Hamiltonian-invariant sections supported on X :

$$\mathrm{Hom}_{\mathcal{D}}(M(f), N) = \Gamma_X(\mathbf{A}^n, N)^{\Omega^{n-3}(\mathbf{A}^n)}, \quad (1.27)$$

where N is any left D-module and $\Gamma_X(\mathbf{A}^n, N) = \{n \in N \mid fn = 0\}$ are the elements of N which are scheme-theoretically supported on X .

The left D-module $M(f)$ and $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ have striking similarities. They are both supported on X and their D-module restrictions to the smooth locus X° of X are both isomorphic to the structure sheaf \mathcal{O}_{X° viewed as a left \mathcal{D}_{X° -module (for $M(f)$, this follows from the corresponding statement for $M(X, \theta)$ in [ES12, Example 2.37]). Moreover, one easily deduces from the

presentation (1.26) that there is a unique morphism of left \mathcal{D} -modules $M(f) \rightarrow \mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ sending 1 to f^s .

DEFINITION 1.28. The canonical morphism $M(f) \xrightarrow{\gamma_f} \mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ is the unique morphism of left \mathcal{D} -modules such that $\gamma_f(1) = f^s$.

Our next main result clarifies the situation when f is quasi-homogeneous with an isolated singularity:

THEOREM 1.29. Let f be a complex polynomial in $n \geq 3$ variables. If f is quasi-homogeneous with an isolated singularity, then γ_f is an isomorphism.

The theorem is proved in Section 3. When f is quasi-homogeneous with an isolated singularity, Theorem 1.29 allows us to use the results of [ES14] on the structure of $M(f)$ to study $\mathcal{D}_{\frac{1}{f}}/R$ and the canonical surjection $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1} \rightarrow \mathcal{D}_{\frac{1}{f}}/R$. It also allows us to describe the precise structure of the \mathcal{D} -module $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$. Let μ_x be the Milnor number of the singularity at x .

COROLLARY 1.30. If f is quasi-homogeneous with an isolated singularity at x , then there is a decomposition $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1} \cong \delta^{\mu_x - g_x} \oplus N$, where N is an indecomposable \mathcal{D} -module admitting a filtration $0 \subseteq N_1 \subseteq N_2 \subseteq N_3 = N$ such that $N_3/N_2 \cong \delta^{g_x}$, $N_2/N_1 \cong \text{IC}(X)$, and $N_1 \cong \delta^{\dim H^{n-2}(X^\circ, \mathbf{C})}$.

Proof. This follows from the theorem together with [ES14, Theorem 2.7, Theorem 3.1, Proposition 3.2], using Lemma 2.5 to obtain the constant g_x and [ES14, (2.9)] (or Lemma 3.5 below) to obtain $\dim H^{n-2}(X^\circ, \mathbf{C})$. \square

REMARK 1.31. It is interesting to ask when the canonical morphism remains surjective or injective in the inhomogeneous case. One simple observation is the following: suppose λ is a root of the b -function such that $\lambda - m$ is not a root for any $m \geq 1$. In this case, it is well-known that the quotient $\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$ is nonzero ([Kas77, Proposition 6.2]). Similarly, one can prove that the image of the canonical map $M(f) \rightarrow \mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ contains the entire generalized eigenspace $(\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1})_{(\lambda)} := \{m \in \mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1} \mid (s - \lambda)^N m = 0, N \gg 0\}$ under s of eigenvalue λ .

REMARK 1.32. Using Corollary 1.30, we can describe the generalized eigenspaces of $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ under multiplication by s . At eigenvalue $\lambda \neq -1$, the generalized eigenspace is just δ^{m_λ} for m_λ given in Corollary 1.20. At eigenvalue $\lambda = -1$, it follows from Theorems 2.1 and 4.4 below that the generalized eigenspace is the indecomposable \mathcal{D} -module N appearing in Corollary 1.30.

REMARK 1.33. The definition of $M(f)$ can be extended to the case when \mathbf{A}^n is replaced by a Calabi–Yau variety, i.e., a smooth variety with a nonvanishing algebraic volume form: we simply replace $\partial_1 \wedge \cdots \wedge \partial_n$ by the inverse of the volume form (see [ES12, §3.4]). Theorem 1.29 generalizes directly to that setting.

1.4 Relation to work of M. Saito

After independently obtaining our results, we were informed by M. Saito of similar results in [Sai15] obtained by different methods. In particular, he describes $\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$ in terms of the V -filtration on $\mathcal{D}[s]f^s$. Combining [Sai15, Corollary 1] with Corollary 1.20 above, we recover the following result, which is essentially [Ste77, Theorem 1] (summing the statement below over all β

yields [Ste77, Theorem 1] except without the statement about the weight filtration). Let $F_{f,0}$ be the Milnor fiber of f around 0. The Milnor cohomology $H^{n-1}(F_{f,0}, \mathbf{C})$ has a natural monodromy action of $\pi_1(\mathbf{C} \setminus \{0\}) \cong \mathbf{Z}$, and we let $H^{n-1}(F_{f,0}, \mathbf{C})_{(\lambda)}$ denote the generalized eigenspace of eigenvalue λ with respect to the standard generator. Let F be the Hodge filtration.

THEOREM 1.34. Let $0 < \beta \leq 1$, $j \in \mathbf{Z}$, and $\lambda := -j - \beta$. If $\lambda \neq -1$, then the vector space $\mathrm{gr}_F^{n-j-1} H^{n-1}(F_{f,0}, \mathbf{C})_{(\exp(-2\pi i\beta))}$ is nonzero if and only if λ is a root of the b -function of f . Moreover, for all λ , we have

$$\mathrm{gr}_F^{n-j-1} H^{n-1}(F_{f,0}, \mathbf{C})_{(\exp(-2\pi i\beta))} \cong J_{-|f|\lambda - \sum_i m_i}. \quad (1.35)$$

In other words, the Jacobi ring is the associated graded vector space of the Milnor cohomology with respect to the Hodge filtration (up to shifting degrees and taking into account the monodromy eigenvalues).

One can in fact show that any two of the results: (1) Corollary 1.20, (2) Steenbrink's Theorem 1.34, and (3) Saito's [Sai15, Corollary 1], imply the third.

1.5 Notations

For the rest of the paper and unless otherwise mentioned, we will use the following notations: R is the ring of complex polynomials in $n \geq 3$ variables and f is a nonconstant element of R . We let

$$\{f = 0\} =: X \xrightarrow{i} \mathbf{A}^n \xleftarrow{j} U := \{f \neq 0\}$$

denote the canonical inclusions. Moreover we note $X^\circ \xrightarrow{j^X} X$ the canonical open embedding, where X° is the smooth locus of X . Let δ_x denote the irreducible D-module supported at a point $x \in X$ and let $(-)^{\vee}$ denote the dual vector space. Finally, for a morphism $S \xrightarrow{\alpha} T$ of varieties, $(\alpha_*, \alpha^*, \alpha_!, \alpha^!)$ denote the usual functors between the bounded derived categories of holonomic D-modules.

2. Proof of Conjecture 1.7 in the quasi-homogeneous case

The goal of this section is to prove the following result:

THEOREM 2.1. Let f be a quasi-homogeneous complex polynomial in $n \geq 3$ variables with an isolated singularity. Then the length of the left \mathcal{D} -submodule of $H_f^1(R)$ generated by $\frac{1}{f}$ is $1 + g$, with g the reduced genus of the singularity.

We will reduce the proof to a statement about $M(f)$, of which much is known thanks to [ES14]. Let us begin with a couple of lemmas.

LEMMA 2.2. Let $V \xrightarrow{j'} Y$ be an open embedding of not necessarily smooth algebraic varieties and let Z be the complement of V in Y . Let M and N be D-modules on V and Y , respectively. Suppose that there is an isomorphism $j'^* N \xrightarrow{\psi} M$, and let $N \xrightarrow{\phi} j'_* M$ be the adjoint morphism. Then $N \xrightarrow{H^0(\phi)} H^0 j'_* M$ is an isomorphism if and only if $\mathrm{Hom}(K, N) = \mathrm{Ext}^1(K, N) = 0$, for all D-modules K on Y which are supported on Z .

Proof. For the only if, let K be a D-module supported on Z . Note that there is a first-quadrant spectral sequence whose (i, k) entry is $\mathrm{Ext}^i(K, H^k j'_* M)$, with differential of degree $(2, -1)$, which converges to $\mathrm{Ext}^{i+k}(K, j'_* M)$. Since on subsequent pages the differential is of degree $(2 + m, -1 -$

m) for $m > 0$, we see that $\text{Ext}^i(K, H^0 j'_* M)$ survives on all pages for $i \leq 1$ and hence to $\text{Ext}^i(K, j'_* M)$. On the other hand, applying adjunction, $\text{Ext}^i(K, j'_* M) \cong \text{Ext}^i(j'^* K, M) = 0$. Therefore $\text{Ext}^i(K, H^0 j'_* M) = 0$ for $i \leq 1$. As a result, $N \cong H^0 j'_* M$ implies that $\text{Hom}(K, N) = \text{Ext}^1(K, N) = 0$.

Let us prove the if part. Assume therefore that $\text{Hom}(K, N) = \text{Ext}^1(K, N) = 0$ for all K supported on Z . Observe that $\ker H^0(\phi) = 0$. Indeed $\ker H^0(\phi)$ and $\text{coker } H^0(\phi)$ are supported on Z since ψ is an isomorphism but then $\text{Hom}(\ker H^0(\phi), N) = 0$, by hypothesis on N . We thus have a short exact sequence:

$$0 \rightarrow N \xrightarrow{H^0(\phi)} H^0 j'_* M \rightarrow \text{coker } H^0(\phi) \rightarrow 0.$$

It has to split since $\text{Ext}^1(\text{coker } H^0(\phi), N) = 0$ by hypothesis. But by adjunction (or the only if part), $\text{Hom}(\text{coker } H^0(\phi), H^0 j'_* M) = 0$, so $\text{coker } H^0(\phi) = 0$. \square

Recall notations from 1.5.

LEMMA 2.3. Suppose that f has an isolated singularity at the origin. Then the left \mathcal{D} -module $H_f^1(R)$ has no submodules supported at the origin. Moreover, we have an isomorphism $H_f^1(R) \cong H^0(i \circ j^X)_* \mathcal{O}_{X^\circ}$.

Proof. The long exact sequence for $0 \rightarrow R \rightarrow R[\frac{1}{f}] \rightarrow H_f^1(R) \rightarrow 0$ yields:

$$0 \rightarrow \text{Hom}(\delta_0, R) \rightarrow \text{Hom}(\delta_0, R[\frac{1}{f}]) \rightarrow \text{Hom}(\delta_0, H_f^1(R)) \rightarrow \text{Ext}^1(\delta_0, R) \rightarrow \dots$$

Moreover, for all ℓ , $\text{Ext}^\ell(\delta_0, R[\frac{1}{f}]) = \text{Ext}^\ell(j^* \delta_0, \mathcal{O}_U) = 0$ by adjunction. Hence it follows that $\text{Ext}^\ell(\delta_0, H_f^1(R)) \cong \text{Ext}^{\ell+1}(\delta_0, R)$ for all ℓ . Since $\text{Ext}^{\ell+1}(\delta_0, R)$ vanishes if $\ell + 1 \neq n$, and $n \geq 3$ by assumption, we certainly have that $\text{Hom}(\delta_0, H_f^1(R)) = 0$, proving the first part of the lemma, as well as $\text{Ext}^1(\delta_0, H_f^1(R)) = 0$. Note finally that $H_f^1(R)$ is supported on X and its restriction to the smooth locus X° is isomorphic to \mathcal{O}_{X° . Hence we may apply Lemma 2.2 to the \mathcal{D} -module on X corresponding to $H_f^1(R)$ and deduce that $H_f^1(R) \cong i_*(H^0 j^X_* \mathcal{O}_{X^\circ}) \cong H^0(i \circ j^X)_* \mathcal{O}_{X^\circ}$, as claimed. \square

We now precisely relate $\mathcal{D}_{\frac{1}{f}}/R$ to $M(f)$. Recall the canonical morphism γ_f from Definition 1.28 and note that it induces a surjective morphism $M(f) \xrightarrow{\alpha_f} \mathcal{D}_{\frac{1}{f}}/R$.

PROPOSITION 2.4. Suppose that f has a unique singularity. Then the kernel of α_f is the maximal submodule of $M(f)$ supported at the singularity.

Proof. We claim that the left \mathcal{D} -module $M(f)$ is holonomic. This is a consequence of [ES12, Corollary 3.37] (and is probably well-known), but let us give a direct proof for the reader's convenience. First note that $M(f)$ is supported on X and the corresponding \mathcal{D} -module on X restricts on X° to the left \mathcal{D}_{X° -module \mathcal{O}_{X° . Therefore the singular support of $M(f)$ is contained in the union of the zero section $X \subseteq T^*X$ and the cotangent fiber T_x^*X at the singularity $x \in X$, which is Lagrangian. This proves the claim.

Let us consider the maximal submodule K of $M(f)$ supported at the singularity. The first assertion of Lemma 2.3 then implies that $\alpha_f(K) = 0$. Let us show that the induced surjective morphism $M(f)/K \xrightarrow{\alpha_f} \mathcal{D}_{\frac{1}{f}}/R$ is injective. We see that $i_* j^X_* \mathcal{O}_{X^\circ}$ is the unique minimal submodule of $M(f)/K$. Hence $\ker \alpha_f$ is either trivial or contains $i_* j^X_* \mathcal{O}_{X^\circ}$. But the latter cannot occur since $\mathcal{D}_{\frac{1}{f}}/R$ is not supported at the singularity. \square

We may now prove Theorem 2.1.

Proof. Let the cone point, i.e., the singularity, be the origin $0 \in X$. As in [ES14], let M_{\max} denote the (unique) indecomposable factor of $M(X, \theta)$ fully supported on X . By Proposition 2.4, the map $M_{\max} \rightarrow \mathcal{D}^{\frac{1}{f}}/R$ is surjective with kernel the maximum submodule of M_{\max} supported at the origin: call this kernel K' . Thus, the lengths of $\mathcal{D}^{\frac{1}{f}}/R$ and M_{\max}/K' are the same. Next, by [ES14, Theorem 3.1], $H^0 j_! \Omega_{X^\circ} \subseteq M_{\max}$, where Ω_{X° is the right D-module of volume forms. Since M_{\max} is indecomposable, K' is also the maximal submodule of $H^0 j_! \Omega_{X^\circ}$ supported at the origin. Since $H^0 j_! \Omega_{X^\circ}$ has no quotient supported at the origin, $H^0 j_! \Omega_{X^\circ}/K'$ must be the minimal extension $\mathrm{IC}(X)$ of Ω_{X° , which is simple. Therefore the length of M_{\max}/K' is $1 + \ell$, with ℓ the length of $M_{\max}/H^0 j_! \Omega_{X^\circ}$. By [ES14, Proposition 3.2], ℓ equals $\dim \Gamma(X, \mathcal{O}_X)_d$, with d the weight of X , that is the degree of f in the grading on R introduced in Subsection 1.2.

It remains to show that $\dim \Gamma(X, \mathcal{O}_X)_d = g$. This is proved in the following lemma. \square

The conclusion relies on the following identity:

LEMMA 2.5. Let f be as in Theorem 2.1, then $\dim \Gamma(X, \mathcal{O}_X)_d = g$.

Proof. Let $0 \in X$ be the singularity. Let $\rho : \tilde{X} \rightarrow X$ be a normal crossings resolution of singularities and $Y := \rho^{-1}(0)$. By definition, $g = \dim H^{n-2}(Y, \mathcal{O}_Y)$. It therefore suffices to prove that $H^{n-2}(Y, \mathcal{O}_Y) \cong \Gamma(X, \mathcal{O}_X)_d$. For this we follow [ES14, §3] (and the corrected online version of Proposition 3.13), providing details for the reader's convenience.

Since Y is a normal crossings divisor, its logarithmic canonical bundle $\Omega_{Y, \log}^{n-2}$, consisting of volume forms on the smooth locus of Y which have only simple poles along the intersections of irreducible components of Y , is isomorphic to the canonical sheaf. By Grothendieck–Serre duality, we obtain that $H^{n-2}(Y, \mathcal{O}_Y) \cong H^0(Y, \Omega_{Y, \log}^{n-2})$. Now, we can form the exact sequence

$$0 \rightarrow \Omega_{\tilde{X}}^{n-1} \rightarrow \Omega_{\tilde{X}}^{n-1}(Y) \rightarrow \Omega_{Y, \log}^{n-2} \rightarrow 0. \quad (2.6)$$

By Grauert–Riemenschneider vanishing, $R^1 \rho_* \Omega_{\tilde{X}}^{n-1} = 0$, and since X is affine, we obtain that $H^1(X, \rho_* \Omega_{\tilde{X}}^{n-1}) = 0$. Therefore $H^1(\tilde{X}, \Omega_{\tilde{X}}^{n-1}) = 0$. By (2.6), we obtain that $\Gamma(Y, \Omega_{Y, \log}^{n-2}) \cong \Gamma(\tilde{X}, \Omega_{\tilde{X}}^{n-1}(Y))/\Gamma(\tilde{X}, \Omega_{\tilde{X}}^{n-1})$. Finally note that $\Gamma(\tilde{X}, \Omega_{\tilde{X}}^{n-1})$ and $\Gamma(\tilde{X}, \Omega_{\tilde{X}}^{n-1}(Y))$ are both subspaces of $\Gamma(X^\circ, \Omega_{X^\circ}^{n-1})$, global volume forms on X° , which is identified with $\Gamma(X^\circ, \mathcal{O}_X) = \Gamma(X, \mathcal{O}_X)$ under the isomorphism sending $dx_1 \wedge \cdots \wedge dx_n/df$ to 1. This isomorphism identifies $\Gamma(\tilde{X}, \Omega_{\tilde{X}}^{n-1})$ with $(\mathcal{O}_X)_{>d}$, since a volume form on X° is a sum of homogeneous forms, and a homogeneous form α extends to \tilde{X} if and only if it is of positive degree, i.e., in some neighborhood U of $0 \in X$, the integral $\lim_{\varepsilon \rightarrow 0} \int_{U \cap \{|f| \geq \varepsilon\}} \alpha \wedge \bar{\alpha}$ converges. Similarly, $\Gamma(\tilde{X}, \Omega_{\tilde{X}}^{n-1}(Y))$ identifies with $(\mathcal{O}_X)_{\geq d}$, since a meromorphic volume form α on \tilde{X} has logarithmic poles at Y if and only if it has nonnegative degree, i.e., the limit $|\log \varepsilon|^{-1} \int_{U \cap \{|f| > \varepsilon\}} \alpha \wedge \bar{\alpha}$ exists for some neighborhood U of $0 \in X$. Put together we obtain an isomorphism $\Gamma(Y, \Omega_{Y, \log}^{n-2}) \cong (\mathcal{O}_X)_d$ as desired. \square

REMARK 2.7. The proof implies that Conjecture 1.7 is equivalent to [ES14, Conjecture 3.8].

3. Proof of Theorem 1.29

We want to show that if f is quasi-homogeneous with an isolated singularity, then the canonical morphism $M(f) \xrightarrow{\gamma_f} \mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ is an isomorphism. Since f is quasi-homogeneous, there is

a vector field v such that $v(f^s) = sf^s$. Thus $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ is generated by f^s as a \mathcal{D} -module and hence γ_f is surjective. We will prove that γ_f is also injective by showing that the lengths of $M(f)$ and $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ are the same.

3.1 Nearby cycles

We will use our running notations and hypotheses, see Subsection 1.5. We set $\mathcal{D}_U := \mathcal{D}[\frac{1}{f}]$ to be the ring of differential operators on U . Let M be a holonomic left \mathcal{D}_U -module M . We denote the nearby cycles \mathcal{D} -module with respect to f by $\Psi_f(M)$ [Kas83, Mal83]. This is a holonomic left \mathcal{D} -module supported on X and is equipped with a log-monodromy operator s , such that the classical monodromy operator T (in the case that M has regular singularities) is given by $T = e^{2\pi is}$.

First and for later use, we would like to relate nearby cycles to the quotients $\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$.

DEFINITION 3.1. Let $\lambda \in \mathbb{C}$. We define:

- (i) $\mathcal{D}f^{\lambda-\infty}$ is the left \mathcal{D} -module $R[\frac{1}{f}]f^\lambda$
- (ii) F is the filtration of $\mathcal{D}f^{\lambda-\infty}$ by \mathcal{D} -submodules given by $F^i\mathcal{D}f^{\lambda-\infty} := \mathcal{D}f^{\lambda+i}$
- (iii) $\mathcal{D}f^{\lambda+\infty}$ is the intersection $\bigcap_{i \in \mathbb{Z}} F^i\mathcal{D}f^{\lambda-\infty}$

REMARK 3.2. Note that the associated graded \mathcal{D} -module $\text{gr}^F \mathcal{D}f^{\lambda-\infty}$ is the sum $\mathcal{D}f^{\lambda+\infty} \oplus \bigoplus_{i \in \mathbb{Z}} \mathcal{D}f^{\lambda+i}/\mathcal{D}f^{\lambda+i+1}$. Clearly the filtration F , and hence the sum, are actually finite, since $\mathcal{D}f^{\lambda-\infty}$ is a holonomic \mathcal{D} -module.

REMARK 3.3. F seems to be closely related to the filtration G used by M. Saito in [Sai15, §1.3].

We will need a precise relationship between nearby cycles and $\mathcal{D}f^{\lambda-\infty}$.

PROPOSITION 3.4. Let $\lambda \in \mathbb{C}$ and let \mathcal{O}_U^λ denote the left \mathcal{D}_U -module $R[\frac{1}{f}]f^\lambda$. Then

- (i) $\mathcal{D}f^{\lambda+\infty} \cong j_{!*}\mathcal{O}_U^\lambda$
- (ii) $\mathcal{D}f^{\lambda-\infty}/\mathcal{D}f^{\lambda+\infty} \cong \text{coker}(\Psi_f(\mathcal{O}_U) \xrightarrow{T-e^{2\pi i\lambda}} \Psi_f(\mathcal{O}_U))$

Proof. This is well-known. The first assertion is [Gin86, lemma 3.8.2]. The second assertion follows by the Riemann-Hilbert correspondence from its perverse sheaf counterpart. The latter is an immediate consequence of [dCM09, Section 5.6 p.617] since $\text{coker}(\Psi_f(\mathcal{O}_U) \xrightarrow{T-e^{2\pi i\lambda}} \Psi_f(\mathcal{O}_U)) \cong \text{coker}(\Psi_f(\mathcal{O}_U^\lambda) \xrightarrow{T-\text{Id}} \Psi_f(\mathcal{O}_U^\lambda))$. \square

We now come to the computation of the length of nearby cycles. We will need the following lemma, which is a generalization of [ES14, (2.9)].

LEMMA 3.5. Suppose X has an isolated singularity at $x \in X$ and let V be a contractible analytic neighborhood of x , such that $V \setminus \{x\}$ is smooth, with $j^V := j^X|_{V \setminus \{x\}} : V \setminus \{x\} \rightarrow V$ the inclusion. Then, the kernel of the canonical surjection $H^0 j_!^V \mathcal{O}_{V \setminus \{x\}} \rightarrow j_{!*} \mathcal{O}_{V \setminus \{x\}}$ is isomorphic to $\delta_x \otimes H^{n-2}(V \setminus \{x\}, \mathbb{C})^\vee$. Similarly, the cokernel of the canonical injection $j_{!*} \mathcal{O}_{V \setminus \{x\}} \rightarrow H^0 j_*^V \mathcal{O}_{V \setminus \{x\}}$ is isomorphic to $\delta_x \otimes H^{n-2}(V \setminus \{x\}, \mathbb{C})$.

The argument closely follows [ES10, Lemma 4.3], but as the statement is more general we provide the proof. Note that in this statement and proof it is not necessary that X be a hypersurface.

Proof. Consider the exact sequence $0 \rightarrow K \rightarrow H^0 j_!^V \mathcal{O}_{V \setminus \{x\}} \rightarrow j_{!*} \mathcal{O}_{V \setminus \{x\}} \rightarrow 0$ with K supported at x . Apply $\text{Hom}(\delta_x, -)$ to obtain the isomorphism

$$\text{Hom}(\delta_x, K) \cong \text{Hom}(\delta_x, H^0 j_!^V \mathcal{O}_{V \setminus \{x\}}).$$

Let $i^x : \{x\} \rightarrow V$ be the closed inclusion. By the adjunction $(i_!, H^0 i^!)$,

$$\text{Hom}(\delta_x, H^0 j_!^V \mathcal{O}_{V \setminus \{x\}}) = H^0 i^! H^0 j_!^V \mathcal{O}_{V \setminus \{x\}}.$$

Now, the cohomology of $j_!^V \mathcal{O}_{V \setminus \{x\}}$ is concentrated in nonpositive degrees (since $j_!^V$ is the left derived functor of the left adjoint $H^0 j_!^V$ of the exact restriction functor $(j^V)^!$). Moreover, $H^{<0} j_!^V \mathcal{O}_{V \setminus \{x\}}$ is concentrated at the singularity x . Therefore $H^0 i^! j_!^V \mathcal{O}_{V \setminus \{x\}} = H^0 i^! H^0 j_!^V \mathcal{O}_{V \setminus \{x\}}$. The former is Verdier dual to $H^0 i_* j_*^V \mathcal{O}_{V \setminus \{x\}}$, which is nothing but the zeroth cohomology of the stalk at x of $j_*^V \mathcal{O}_{V \setminus \{x\}}$, i.e., the cohomology $H^{\dim V}(V \setminus \{x\}, \mathbf{C}) = H^{n-2}(V \setminus \{x\}, \mathbf{C})$. This proves the first assertion. The second assertion follows from the first by Verdier duality. \square

PROPOSITION 3.6. Suppose that f is quasi-homogeneous with an isolated singularity. Then the length of the nearby cycles \mathcal{D} -module $\Psi_f(\mathcal{O}_U)$ is $1 + \mu + \dim H^{n-2}(X^\circ, \mathbf{C})$, with μ the Milnor number of the singularity.

Proof. By Proposition 3.4, we have $H_f^1(R) \cong \mathcal{D}f^{-1-\infty}/\mathcal{D}f^{-1+\infty} \cong \text{coker}(\Psi_f(\mathcal{O}_U) \xrightarrow{T-Id} \Psi_f(\mathcal{O}_U))$. Moreover, by Lemma 2.3, $H_f^1(R) \cong H^0(i \circ j^X)_* \mathcal{O}_{X^\circ}$. Hence there is a short exact sequence $0 \rightarrow K \rightarrow \Psi_f(\mathcal{O}_U) \rightarrow H^0(i \circ j^X)_* \mathcal{O}_{X^\circ} \rightarrow 0$, with K supported at the singularity. Applying Verdier duality, we get a short exact sequence $0 \rightarrow i_* H^0 j_!^X \mathcal{O}_{X^\circ} \rightarrow \Psi_f(\mathcal{O}_U) \rightarrow K \rightarrow 0$. By duality, it follows from Lemma 2.3 that $i_* H^0 j_!^X \mathcal{O}_{X^\circ}$ has no quotient supported at the singularity. Hence K is isomorphic to the maximal quotient $i_{x*} H^0 i_x^* \Psi_f(\mathcal{O}_U)$ of $\Psi_f(\mathcal{O}_U)$ supported at the singularity $x \xrightarrow{i_x} \mathbf{A}^n$. But $H^0 i_x^* \Psi_f(\mathcal{O}_U)$ is isomorphic to the top reduced cohomology of the Milnor fiber of x and hence has dimension μ . We thus have that the length $lg(\Psi_f(\mathcal{O}_U))$ of $\Psi_f(\mathcal{O}_U)$ is $lg(i_* H^0 j_!^X \mathcal{O}_{X^\circ}) + \mu$. The proposition now follows directly from Lemma 3.5. \square

COROLLARY 3.7. Suppose that f is quasi-homogeneous with an isolated singularity. Then the \mathcal{D} -module length of $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ is $1 + \mu + \dim H^{n-2}(X^\circ, \mathbf{C})$, with μ the Milnor number of the singularity.

Proof. By [Gin86, Proposition 5.6], $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ and $\Psi_f(\mathcal{O}_U)$ have the same length. Hence the statement is equivalent to Proposition 3.6. \square

3.2 Length of $M(f)$

PROPOSITION 3.8. Suppose that f is quasi-homogeneous with an isolated singularity. Then the \mathcal{D} -module length of $M(f)$ is $1 + \mu + \dim H^{n-2}(X^\circ, \mathbf{C})$, with μ the Milnor number of the singularity.

Proof. By [ES14, Theorem 2.7], there is a short exact sequence $0 \rightarrow i_* H^0 j_!^X \mathcal{O}_{X^\circ} \rightarrow M(f) \rightarrow \delta^\mu \rightarrow 0$. Hence the proposition follows from Lemma 3.5. \square

The theorem easily follows:

Proof of Theorem 1.29. The canonical morphism $M(f) \xrightarrow{\gamma_f} \mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ is surjective since f is quasi-homogeneous, as explained at the beginning of the section. Since $M(f)$ has the same length as $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ by Proposition 3.8 and Corollary 3.7, γ_f is also injective. \square

4. Proof of Theorem 1.19 and the quotients $\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$

The following notion is central to our proof.

DEFINITION 4.1. Let $Z \xrightarrow{i_Z} \mathbf{A}^n$ be a closed embedding and let M be a holonomic left \mathcal{D} -module. Then the holonomic \mathcal{D} -module $\text{db}_Z(M)$ supported on Z is $i_{Z*} \ker(H^0 i_Z^! M \rightarrow H^0 i_Z^* M)$.

Here “db” stands for “deltas on the bottom.”

REMARK 4.2. It follows directly from the definition that $\text{db}_Z(M)$ is the kernel of the canonical map from the maximal submodule of M supported at Z to the maximal quotient of M supported at Z .

We need the following easy lemma on db_Z :

LEMMA 4.3. (i) Let $M \xrightarrow{\alpha} N$ be a morphism of holonomic \mathcal{D} -modules. Then $\alpha(\text{db}_Z(M)) \subseteq \text{db}_Z(N)$.

(ii) The formation of db_Z commutes with finite direct sums.

Proof. It follows easily from the description of db_Z in Remark 4.2. \square

We will deduce Theorem 1.19 from the following. We let $(\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1})_{(\lambda)}$ be the generalized eigenspace under s of eigenvalue λ .

THEOREM 4.4. Suppose that f is quasi-homogeneous with an isolated singularity at 0. Let p be the surjective morphism $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1} \xrightarrow{\Sigma \lambda p_\lambda} \bigoplus_\lambda \mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$, where p_λ is the natural surjection $(\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1})_{(\lambda)} \rightarrow \mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$. Then $\ker p = \ker p_{-1}$ is the submodule $\text{db}_{\{0\}}(\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1})$, and the latter is isomorphic to $\delta^{\dim H^{n-2}(X^\circ, \mathbb{C})}$.

Proof. Let us first prove that $\text{db}_{\{0\}}(\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1})$ is isomorphic to $\delta^{\dim H^{n-2}(X^\circ, \mathbb{C})}$. By [ES14, Theorem 2.7], there is a short exact sequence $0 \rightarrow i_* H^0 j_1^X \mathcal{O}_{X^\circ} \rightarrow M(f) \rightarrow \delta^\mu \rightarrow 0$ and the map $M(f) \rightarrow \delta^\mu$ is the maximal quotient of $M(f)$ supported at the origin. Hence $\text{db}_{\{0\}}(M(f))$ is the maximal submodule of $i_* H^0 j_1^X \mathcal{O}_{X^\circ}$ supported at the origin. By Lemma 3.5, the latter is isomorphic to $\delta^{\dim H^{n-2}(X^\circ, \mathbb{C})}$. The claim thus follows from Theorem 1.29.

We now prove that $\text{db}_{\{0\}}(\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}) \subseteq \ker p$. We have $\text{db}_{\{0\}}(\bigoplus_\lambda \mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}) = 0$. Indeed, by (ii) of Lemma 4.3, it suffices to check that $\text{db}_{\{0\}}(\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1})$ vanishes for all λ . For $\lambda \neq -1$, $\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$ is supported at the origin hence $\text{db}_{\{0\}}(\mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}) = 0$. Moreover by Lemma 2.3, $\mathcal{D}f^{-1}/R \subseteq H_f^1(R)$ does not have any submodule supported at the origin. Thus $\text{db}_{\{0\}}(\mathcal{D}f^{-1}/R) = 0$. We conclude by (i) of Lemma 4.3.

Let us then show that the length of $\ker p$ is at most $\dim H^{n-2}(X^\circ, \mathbb{C})$. This immediately implies that $\ker p$ is isomorphic to $\text{db}_{\{0\}}(\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1})$. We claim that the length of the module $\bigoplus_\lambda \mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$ is at least $1 + \mu$. Since by Corollary 3.7, the length of $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ is $1 + \mu + \dim H^{n-2}(X^\circ, \mathbb{C})$, the claim indeed implies the upper-bound on the length of $\ker p$. By Remark 3.2 and Proposition 3.4, $\bigoplus_\lambda \mathcal{D}f^\lambda/\mathcal{D}f^{\lambda+1}$ is the associated graded module to a finite filtration on $M := \bigoplus_{\lambda \in \mathbb{C}/\mathbb{Z}} \text{coker}(\Psi_f(\mathcal{O}_U) \xrightarrow{T - e^{2\pi i \lambda}} \Psi_f(\mathcal{O}_U))$. Hence their lengths are the same. Let $\{0\} \xrightarrow{i_0} \mathbb{A}^n$ be the embedding of the origin. Since $i_{0*} H^0 i_0^*$ is right-exact, we have that the maximal quotient $i_{0*} H^0 i_0^* M$ of M supported at the origin is $\bigoplus_{\lambda \in \mathbb{C}/\mathbb{Z}} \text{coker}(i_{0*} H^0 i_0^* \Psi_f(\mathcal{O}_U) \xrightarrow{T - e^{2\pi i \lambda}} i_{0*} H^0 i_0^* \Psi_f(\mathcal{O}_U))$. But the stalk $H^0 i_0^* \Psi_f(\mathcal{O}_U)$ of the nearby cycles at the origin is the top reduced

cohomology of the Milnor fiber of the origin, on which the induced action of T is the usual monodromy. Since the monodromy action is semisimple, see for example [Dim04, Chapter 3, Example 1.19], it follows that the natural surjection $i_{0*}H^0i_0^*\Psi_f(\mathcal{O}_U) \rightarrow i_{0*}H^0i_0^*M$ is an isomorphism. Hence the maximal quotient $i_{0*}H^0i_0^*M$ of M supported at the origin is of length μ . But M contains $H_f^1(R)$ and hence is not supported at the origin. Thus its length is at least $1 + \mu$, as claimed.

Finally, we have that $\text{db}_{\{0\}}(\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}) \subset (\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1})_{(-1)}$, since the other generalized eigenspaces of $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ under s are supported at the origin. Hence

$$\text{db}_{\{0\}}(\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}) = \ker p = \ker p_{-1}.$$

This concludes the proof of the theorem. \square

Proof of Theorem 1.19. By Theorem 4.4, $\ker p = \ker p_{-1}$. Hence for all $\lambda \neq -1$, $\ker q_\lambda = 0$. Point (i) immediately follows.

We now prove point (ii) of the theorem. By definition of $\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}|_{s=-1}$, we have a short exact sequence:

$$0 \rightarrow ((s+1)\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1})_{(-1)} \rightarrow (\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1})_{(-1)} \xrightarrow{\pi} \mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}|_{s=-1} \rightarrow 0$$

We have $p_{-1} = q_{-1} \circ \pi$. Hence the kernel $\ker q_{-1}$ is the image $\pi(\ker p_{-1})$. But by [Kas03, Theorem 6.18], s acts semisimply on $(s+1)\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1}$ and $((s+1)\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1})|_{s=-1} = ((s+1)\mathcal{D}[s]f^s/\mathcal{D}[s]f^{s+1})_{(-1)} = \ker \pi$ is isomorphic to δ^{g_0} . The result now follows since $\ker p_{-1}$ is isomorphic to $\delta^{\dim H^{n-2}(X^\circ, \mathbb{C})}$ by Theorem 4.4. \square

ACKNOWLEDGEMENTS

We are grateful to Pavel Etingof for initially suggesting a relationship between $M(X, \theta)$ and $\mathcal{D}_f^1/\mathcal{O}$. We would like to thank Uli Walther for useful discussions, particularly for suggesting that Question 1.17 should have an affirmative answer in the quasi-homogeneous isolated singularity case, and Johannes Nicaise for pointing out the semisimplicity of monodromy and the reference [Dim04], as well as for many useful discussions.
