# Trivial zeros of $p$-adic $L$-functions at near central points (second version) 

Denis Benois

September 5th 2012

Using the $\ell$-invariant constructed in our previous paper we prove a Mazur-Tate-Teitelbaum style formula for derivatives of $p$-adic $L$-functions of modular forms at near central points.

## §0. Introduction

0.1. Trivial zeros of modular forms. In this paper we prove a Mazur-Tate-Teitelbaum style formula for the values of derivatives of $p$-adic $L$-functions of modular forms at near central points. Together with the results of Kato-Kurihara-Tsuji and Greenberg-Stevens on the Mazur-Tate-Teitelbaum conjecture this gives a complete proof of the trivial zero conjecture formulated in [Ben2] for elliptic modular forms. Namely, let $f=\sum_{n=1}^{\infty} a_{n} q^{n}$ be a normalized newform on $\Gamma_{0}(N)$ of weight $k \geqslant 2$ and character $\varepsilon$ and let $L(f, s)=\sum_{n=1}^{\infty} a_{n} n^{-s}$ be the complex $L$-function associated to $f$. It is well known that $L(f, s)$ converges for $\operatorname{Re}(s)>\frac{k+1}{2}$ and decomposes into an Euler product

$$
L(f, s)=\prod_{l} E_{l}\left(f, l^{-s}\right)^{-1}
$$

where $l$ runs over all primes and $E_{l}(f, X)=1-a_{l} X+\varepsilon(l) l^{k-1} X^{2}$. Moreover $L(f, s)$ has an analytic continuation on the whole complex plane and satisfies the functional equation

$$
(2 \pi)^{-s} \Gamma(s) L(f, s)=i^{k} c N^{k / 2-s}(2 \pi)^{s-k} \Gamma(k-s) L\left(f^{*}, k-s\right)
$$

where $f^{*}=\sum_{n=1}^{\infty} \bar{a}_{n} q^{n}$ is the dual cusp form and $c$ is some constant (see for example [Mi, Theorems 4.3.12 and 4.6.15]). More generally, to any Dirichlet character $\eta$ we can associate the $L$-function

$$
L(f, \eta, s)=\sum_{n=1}^{\infty} \frac{\eta(n) a_{n}}{n^{s}}
$$

The theory of modular symbols implies that there exist non-zero complex numbers $\Omega_{f}^{+}$and $\Omega_{f}^{-}$such that for any Dirichlet character $\eta$ one has

$$
\begin{equation*}
\widetilde{L}(f, \eta, j)=\frac{\Gamma(j)}{(2 \pi i)^{j-1} \Omega_{f}^{ \pm}} L(f, \eta, j) \in \overline{\mathbb{Q}}, \quad 1 \leqslant j \leqslant k-1 \tag{1}
\end{equation*}
$$

where $\pm=(-1)^{j-1} \eta(-1)$. Fix a prime number $p>2$ such that the Euler factor $E_{p}(f, X)$ is not equal to 1 . Let $\alpha$ be a root of the polynomial $X^{2}-a_{p} X+\varepsilon(p) p^{k-1}$ in $\overline{\mathbb{Q}}_{p}$. Denote by $v_{p}$ the $p$-adic valuation on $\overline{\mathbb{Q}}_{p}$ normalized such that $v_{p}(p)=1$. Assume that $\alpha$ is not critical i.e. that $v_{p}(\alpha)<k-1$. Let $\omega:(\mathbb{Z} / p \mathbb{Z})^{*} \rightarrow \mathbb{Q}_{p}^{*}$ denote the Teichmüller character. Manin [Mn], Vishik [Vi] and independently Amice-Velu [AV] constructed analytic $p$-adic $L$-functions $L_{p, \alpha}\left(f, \omega^{m}, s\right)$ which interpolate algebraic parts of special values of $L(f, s)^{1}$. Namely, the interpolation property writes

$$
L_{p, \alpha}\left(f, \omega^{m}, j\right)=\mathcal{E}_{\alpha}\left(f, \omega^{m}, j\right) \widetilde{L}\left(f, \omega^{j-m}, j\right), \quad 1 \leqslant j \leqslant k-1
$$

where $\mathcal{E}_{\alpha}\left(f, \omega^{m}, j\right)$ is an explicit Euler like factor. One says that $L_{p, \alpha}\left(f, \omega^{m}, s\right)$ has a trivial zero at $s=j$ if $\mathcal{E}_{\alpha}\left(f, \omega^{m}, j\right)=0$ and $\widetilde{L}\left(f, \omega^{j-m}, j\right) \neq 0$. This phenomenon was first studied by Mazur, Tate and Teitelbaum in [MTT] where the following cases were distinguished:

- The semistable case: $p \| N, k$ is even and $\alpha=a_{p}=p^{k / 2-1}$. The $p$-adic $L$-function $L_{p, \alpha}\left(f, \omega^{k / 2}, s\right)$ has

[^0]a trivial zero at the central point $s=k / 2$.

- The crystalline case: $p \nmid N, k$ is odd and either $\alpha=p^{\frac{k-1}{2}}$ or $\alpha=\varepsilon(p) p^{\frac{k-1}{2}}$. The $p$-adic $L$-function $L_{p, \alpha}\left(f, \omega^{\frac{k+1}{2}}, s\right)$ (respectively $L_{p, \alpha}\left(f, \omega^{\frac{k-1}{2}}, s\right)$ ) has a trivial zero at the near central point $s=\frac{k+1}{2}$ (respectively $s=\frac{k-1}{2}$ ).
-The potentially crystalline case: $p \mid N, k$ is odd and $\alpha=a_{p}=p^{\frac{k-1}{2}}$. The $p$-adic $L$-function $L_{p, \alpha}\left(f, \omega^{\frac{k+1}{2}}, s\right)$ has a trivial zero at the near central point $s=\frac{k+1}{2}$.
0.2. The semistable case. Let

$$
\rho_{f}: \operatorname{Gal}(\overline{\mathbb{Q}} / \mathbb{Q}) \rightarrow \operatorname{GL}\left(W_{f}\right) .
$$

be the $p$-adic Galois representation associated to $f$ by Deligne [D1]. Assume that $k$ is even, $p \| N$ and $a_{p}=p^{k / 2-1}$. Then the restriction of $\rho_{f}$ on the decomposition group at $p$ is semistable and non-crystalline in the sense of Fontaine [Fo3]. The associated filtered $(\varphi, N)$-module $\mathbf{D}_{\text {st }}\left(W_{f}\right)$ has a basis $e_{\alpha}, e_{\beta}$ such that $e_{\alpha}=N e_{\beta}, \varphi\left(e_{\alpha}\right)=a_{p} e_{\alpha}$ and $\varphi\left(e_{\beta}\right)=p a_{p} e_{\beta}$. The jumps of the canonical decreasing filtration of $\mathbf{D}_{\text {st }}\left(W_{f}\right)$ are 0 and $k-1$ and the $\mathscr{L}$-invariant of Fontaine-Mazur is defined to be the unique element $\mathscr{L}_{\mathrm{FM}}(f) \in \overline{\mathbb{Q}}_{p}$ such that $\mathrm{Fil}^{k-1} \mathbf{D}_{\text {st }}\left(V_{f}\right)$ is generated by $e_{\beta}+\mathscr{L}_{\mathrm{FM}}(f) e_{\alpha}$. In [MTT] Mazur, Tate and Teitelbaum conjectured that

$$
\begin{equation*}
L_{p, \alpha}\left(f, \omega^{k / 2}, k / 2\right)=\mathscr{L}_{\mathrm{FM}}(f) \widetilde{L}(f, k / 2) . \tag{2}
\end{equation*}
$$

We remark that $L(f, k / 2)$ can vanish. The conjecture (2) was proved in [GS] in the weight two case and in [St] in general using the theory of $p$-adic families of modular forms. Another proof, based on the theory of Euler systems was found by Kato, Kurihara and Tsuji (unpublished but see [Ka2], [PR5], [Cz3]). Note that in [St] Stevens uses another definition of the $\mathscr{L}$-invariant proposed by Coleman [Co]. We refer to $[\mathrm{CI}]$ and to the survey article $[\mathrm{Cz} 4]$ for further information and references.
0.3. The general case. Our main aim in this paper is to prove an analogue of the formula (2) in the crystalline and potentially crystalline cases. In fact, we will treat all three cases simultaneously. Let $f$ be a newform of weight $k$. Fix an odd prime $p$ and assume that the $p$-adic $L$-function $L_{p, \alpha}\left(f, \omega^{k_{0}}, s\right)$ has a trivial zero at $s=k_{0}$. Assume further that $k_{0} \geqslant k / 2$. Note that the last assumption holds automatically in the semistable and potentially crystalline cases and in the crystalline case it is not restrictive because we can use the functional equation (see Remark 3 below). Let $\mathbf{D}_{\text {cris }}\left(W_{f}\right)$ denote the crystalline module associated to $W_{f}$. Our assumptions imply that $\mathbf{D}_{\text {cris }}\left(W_{f}\left(k_{0}\right)\right)^{\varphi=p^{-1}}$ is a onedimensional vector space which we denote by $D_{\alpha}$. The main construction of [Ben2] associates to $D_{\alpha}$ an element $\ell\left(W_{f}\left(k_{0}\right), D_{\alpha}\right) \in \overline{\mathbb{Q}}_{p}$ which can be viewed as a direct generalization of Greenberg's $\ell$-invariant [Gre1] to the non-ordinary case ${ }^{2}$. To simplify notation we set $\ell_{\alpha}(f)=\ell\left(W_{f}\left(k_{0}\right), D_{\alpha}\right)$. The main result of this paper states as follows.

Theorem. Let $f$ be a newform on $\Gamma_{0}(N)$ of character $\varepsilon$ and weight $k$ and let $p$ be an odd prime. Assume that the p-adic L-function $L_{p, \alpha}\left(f, \omega^{k_{0}}, s\right)$ has a trivial zero at $s=k_{0} \geqslant k / 2$. Then

$$
L_{p, \alpha}^{\prime}\left(f, \omega^{k_{0}}, k_{0}\right)=\ell_{\alpha}(f)\left(1-\frac{\varepsilon(p)}{p}\right) \widetilde{L}\left(f, k_{0}\right) .
$$

[^1]Remarks. 1) In the semistable case $\ell_{\alpha}(f)=\mathscr{L}_{\mathrm{FM}}(f)$ (see [Ben2, Proposition 2.3.7]), $\varepsilon(p)=0$ and we recover the Mazur-Tate-Teitelbaum conjecture. Our proof in this case can be seen as an interpretation of Kato-Kurihara-Tsuji's approach in terms of $(\varphi, \Gamma)$-modules. In the crystalline case some version of our formula was proved by Orton [Or] (unpublished). She does not use ( $\varphi, \Gamma$ )-modules and works with an ad hoc definition of the $\ell$-invariant in terms of Bloch-Kato exponential map in the spirit of [PR4].
2) In the crystalline and potentially crystalline cases $\widetilde{L}\left(f, k_{0}\right)$ does not vanish by the theorem of Jacquet-Shalika [JS].
3) In the crystalline case, trivial zeros at the symmetric point $s=\frac{k-1}{2}$ can be easily studied using the functional equation for $p$-adic $L$-functions [MTT, $\S 17]$. If $\alpha=p^{(k-1) / 2}$ and therefore $L_{p, \alpha}\left(f, \omega^{\frac{k+1}{2}}, s\right)$ has a trivial zero at $s=\frac{k+1}{2}$, then $\alpha^{*}=\varepsilon^{-1}(p) \alpha$ is a root of the Hecke polynomial associated to the dual form $f^{*}=\sum_{n=1}^{\infty} \bar{a}_{n} q^{n}$ and $L_{p, \alpha^{*}}\left(f^{*}, \omega^{\frac{k-1}{2}}, s\right)$ has a trivial zero at $s=\frac{k-1}{2}$. Using the compatibility of the trivial zero conjecture with the functional equation [Ben2, Section 2.3.5] (or just repeating the proof of the main theorem with obvious modifications) we obtain a trivial zero formula for $L_{p, \alpha^{*}}^{\prime}\left(f^{*}, \omega^{\frac{k-1}{2}}, \frac{k-1}{2}\right)$
4) The $\mathscr{L}$-invariant of Fontaine-Mazur which appears in semistable case (2) is local i.e. it depends only on the restriction of the $p$-adic representation $\rho_{f}$ on the decomposition group at $p$. However, in the crystalline and potentially crystalline cases our $\ell$-invariant is global and contains information about the localisation map $H^{1}\left(\mathbb{Q}, W_{f}\left(\frac{k+1}{2}\right)\right) \rightarrow H^{1}\left(\mathbb{Q}_{p}, W_{f}\left(\frac{k+1}{2}\right)\right)$. We remark that in the semistable case the $p$-adic $L$-function has a zero at the central point and in the crystalline and potentially crystalline cases it has a zero at a near central point.
5) Let $\eta$ be a Dirichlet character of conductor $M$ with $(p, M)=1$. The study of trivial zeros of $L_{p, \alpha}\left(f, \eta \omega^{\frac{k+1}{2}}, s\right)$ reduces to our situation by considering the newform $f \otimes \eta$ associated to $f_{\eta}=$ $\sum_{n=1}^{\infty} \eta(n) a_{n} q^{n}$ (see Section 4.1.3).
Our theorem follows from a formula for the derivative of Perrin-Riou exponential map [PR2] in terms of the $\ell$-invariant which we prove in Propositions 2.2.2 and 2.2.4 below applied to the Euler system constructed by Kato [Ka].
0.4. Trivial zeros of Dirichlet $L$-functions. Let $\eta$ be a primitive Dirichet character modulo $N$ and let $p \nmid N$ be a fixed prime. The $p$-adic $L$-function of Kubota-Leopoldt $L_{p}(\eta \omega, s)$ satisfies the interpolation property

$$
L_{p}(\eta \omega, 1-j)=\left(1-\left(\eta \omega^{1-j}\right)(p) p^{j-1}\right) L\left(\eta \omega^{1-j}, 1-j\right), \quad j \geqslant 1 .
$$

Assume that $\eta$ is odd and $\eta(p)=1$. Then $L(\eta, 0) \neq 0$ but the Euler like factor $1-\left(\eta \omega^{1-j}\right)(p) p^{j-1}$ vanishes at $j=1$ and $L_{p}(\eta \omega, s)$ has a trivial zero at $s=0$. Fix a finite extension $L / \mathbb{Q}_{p}$ containing the values of $\eta$. Let $\chi$ denote the cyclotomic character and let ord ${ }_{p}: \operatorname{Gal}\left(\mathbb{Q}_{p}^{\mathrm{ur}} / \mathbb{Q}_{p}\right) \rightarrow L$ be the character defined by $\operatorname{ord}_{p}\left(\operatorname{Fr}_{p}\right)=-1$ where $\operatorname{Fr}_{p}$ is the geometric Frobenius. Then $H^{1}\left(\mathbb{Q}_{p}, L\right)=\operatorname{Hom}\left(\operatorname{Gal}\left(\mathbb{Q}_{p}^{\text {ab }} / \mathbb{Q}_{p}\right), L\right)$ is the two-dimensional $L$-vector space generated by $\log \chi$ and $\operatorname{ord}_{p}$. Since $p \nmid N$ and $\eta(p)=1$ the restriction of $L(\eta)$ on the decomposition group at $p$ is a trivial representation. The localization map

$$
\kappa_{\eta}: H^{1}(\mathbb{Q}, L(\eta)) \rightarrow H^{1}\left(\mathbb{Q}_{p}, L\right)
$$

is injective and identifies $H^{1}(\mathbb{Q}, L(\eta))$ with a one-dimensional subspace of $H^{1}\left(\mathbb{Q}_{p}, L\right)$. It can be shown that $\operatorname{Im}\left(\kappa_{\eta}\right)$ is generated by an element of the form

$$
\begin{equation*}
\log \chi+\mathscr{L}(\eta) \operatorname{ord}_{p} \tag{3}
\end{equation*}
$$

there $\mathscr{L}(\eta) \in L$ is necessarily unique. Applying Proposition 2.2.4 to the Euler system of cyclotomic units we obtain a new proof of the trivial zero conjecture for Dirichlet $L$-functions

$$
\begin{equation*}
L_{p}^{\prime}(\eta \omega, 0)=-\mathscr{L}(\eta) L(\eta, 0) \tag{4}
\end{equation*}
$$

This formula was first proved in [Gro] as the combination of the result of Ferrero-Greenberg [FG] giving an explicit formula for $L_{p}^{\prime}(\eta \omega, 0)$ in terms of the $p$-adic $\Gamma$-function and the Gross-Koblitz formula [GK]. We also remark that Dasgupta, Darmon and Pollack [DDP] recently generalized (4) to totally real number fields $F$ assuming Leopoldt's conjecture and some additional condition on the vanishing of $p$ adic $L$-functions.
0.5. The plan of the paper. The main contents of this article is as follows. In $\S 1$ we review the necessary preliminaries. In particular, Sections 1.1-1.2 are devoted to the theory of $(\varphi, \Gamma)$-modules which plays a key role in our definition of the $\ell$-invariant. In Section 1.3 we review the construction and main properties of Perrin-Riou's large exponential map. In $\S 2$ we review the construction of the $\ell$-invariant $\ell(V, D)$ from [Ben2] and prove an explicit formula for the derivative of the large logarithmic map in terms of $\ell(V, D)$ and the dual exponential map. In $\S 3$ we apply this formula to Dirichlet $L$-functions and give a new proof of (4). Trival zeros of modular forms are studied in $\S 4$. In Section 4.1 we review basic results about $p$-adic $L$-functions of modular forms and the representation $W_{f}$. In Section 4.2 we specialize the general definition of the $\ell$-invariant to the case of modular forms. Finally in Section 4.3 we prove the main theorem.

Acknowledgements. I am grateful to Pierre Parent for a number of very valuable discussions. A part of this work was done during my stay at the Max-Planck-Institut für Mathematik from March to May 2012. I would like to thank the institut for this invitation and excellent working conditions.

## §1. Preliminaries

## 1.1. $(\varphi, \Gamma)$-modules.

1.1.1. Definition of $(\varphi, \Gamma)$-modules (see [Fo1], $[\mathrm{CC} 1],[\mathrm{Cz5}])$. Let $\overline{\mathbb{Q}}_{p}$ be a fixed algebraic closure of $\mathbb{Q}_{p}$. We denote by $C$ the $p$-adic completion of $\overline{\mathbb{Q}}_{p}$ and $v_{p}: C \rightarrow \mathbb{R} \cup\{\infty\}$ the $p$-adic valuation normalized so that $v_{p}(p)=1$ and set $|x|_{p}=\left(\frac{1}{p}\right)^{v_{p}(x)}$. Write $B(r, 1)$ for the $p$-adic annulus $B(r, 1)=$ $\left\{x \in C\left|r \leqslant|x|_{p}<1\right\}\right.$. Fix a system of primitive roots of unity $\varepsilon=\left(\zeta_{p^{n}}\right)_{n \geqslant 0}$, such that $\zeta_{p^{n}}^{p}=\zeta_{p^{n-1}}$ for all $n$. If $K$ is a finite extension of $\mathbb{Q}_{p}$ we set $G_{K}=\operatorname{Gal}\left(\overline{\mathbb{Q}}_{p} / K\right), K_{n}=K\left(\zeta_{p^{n}}\right)$ and $K_{\infty}=\bigcup_{n=0}^{\infty} K_{n}$. Put $\Gamma_{K}=\operatorname{Gal}\left(K_{\infty} / K\right)$ and denote by $\chi: \Gamma_{K} \rightarrow \mathbb{Z}_{p}^{*}$ the cyclotomic character. We write $O_{K}$ for the ring of integers of $K, K_{0}$ for the maximal unramified subextension of $K$ and $\sigma$ for the absolute Frobenius of $K_{0} / \mathbb{Q}_{p}$.

For any $r>0$ let $\mathbf{B}_{K}^{\dagger, r}$ denote the ring of overconvergent elements of Fontaine's ring $\mathbf{B}_{K}$ (see [CC1], [Ber1]). Note that $\mathbf{B}_{K}^{\dagger, r_{1}} \subset \mathbf{B}_{K}^{\dagger, r_{2}}$ if $r_{1} \leqslant r_{2}$. The ring $\mathbf{B}_{K}$ is equipped with a continuous action of $\Gamma_{K}$ and a Frobenius operator $\varphi$ which commute to each other. We remark that $\mathbf{B}_{K}^{\dagger, r}$ are stable under the action of $\Gamma_{K}$ and that $\varphi\left(\mathbf{B}_{K}^{\dagger, r}\right) \subset \mathbf{B}_{K}^{\dagger, p r}$ for all $r$. The following description of $\mathbf{B}_{K}^{\dagger, r}$ is sufficent for the goals of this paper. Let $F$ denote the maximal unramified subextension of $K_{\infty} / K_{0}$ and let $e=\left[K_{\infty}: K_{0}\left(\zeta_{p^{\infty}}\right)\right]$. For any $0 \leqslant s<1$ define

$$
\begin{aligned}
& \mathscr{R}^{(s)}(K)=\left\{f\left(X_{K}\right)=\sum_{k \in \mathbb{Z}} a_{k} X_{K}^{k} \mid a_{k} \in F \text { and } f \text { is holomorphic on } B(s, 1)\right\} \\
& \mathscr{E}^{(s)}(K)=\left\{f\left(X_{K}\right)=\sum_{k \in \mathbb{Z}} a_{k} X_{K}^{k} \mid a_{k} \in F \text { and } f \text { is holomorphic and bounded on } B(s, 1)\right\} .
\end{aligned}
$$

Then there exists $r(K)>0$ such that for all $r>r(K)$ the ring $\mathbf{B}_{K}^{\dagger, r}$ is isomorphic to $\mathscr{E}^{\left(p^{-1 / e r}\right)}(K)$. Here the group $\Gamma_{K}$ acts trivially on the coefficients of power series and $\varphi$ acts on $\mathscr{E}^{\left(p^{-1 / e r)}\right.}(K) \sigma$-semilineary.

In general, the action of $\Gamma_{K}$ and $\varphi$ on $X_{K}$ is very complicated. The situation is more simple when $K=K_{0}$ i.e. $K$ is absolutely unramified. In this case $F=K_{0}$ and we will write $X$ instead $X_{K}$. One has

$$
\begin{aligned}
& \tau f(X)=f(\tau(X)), \quad \text { where } \tau(X)=(1+X)^{\chi(\tau)}-1, \quad \tau \in \Gamma_{K}, \\
& \varphi f(X)=f^{\sigma}(\varphi(X)), \quad \text { where } \varphi(X)=(1+X)^{p}-1 .
\end{aligned}
$$

We come back to the general case. The union $\mathbf{B}_{K}^{\dagger}=\cup_{r>0} \mathbf{B}_{K}^{\dagger, r}$ is a field which is stable under the actions of $\Gamma_{K}$ and $\varphi$ and is isomorphic to $\mathscr{E}^{\dagger}(K)=\underset{0 \leqslant s<1}{\cup} \mathscr{E}^{(s)}(K)$. The operator $\varphi$ has a left inverse given by

$$
\psi(f)=\frac{1}{p} \varphi^{-1}\left(\operatorname{Tr}_{\left.\mathscr{E} \dagger(K) / \varphi\left(\mathscr{E}^{\dagger} \dagger K\right)\right)}(f)\right) .
$$

If $K=K_{0}$ we can also write

$$
\psi(f(X))=\frac{1}{p} \varphi^{-1}\left(\sum_{\zeta^{p}=1} f(\zeta(1+X)-1)\right) .
$$

The field $\mathscr{E}^{\dagger}(K)$ is endowed with the valuation

$$
w\left(\sum_{k \in \mathbb{Z}} a_{k} X^{k}\right)=\min \left\{v_{p}\left(a_{k}\right) \mid k \in \mathbb{Z}\right\}
$$

and we denote by $\mathcal{O}_{\mathscr{E} \dagger(K)}$ its ring of integers.
Set $\mathscr{R}(K)=\underset{0 \leqslant s<1}{\cup} \mathscr{R}^{(s)}(K)$. The actions of $\Gamma_{K}, \varphi$ and $\psi$ can be extended to $\mathscr{R}(K)$ by continuity. If $K \subset K^{\prime}$ then the natural inclusions $\mathbf{B}_{K}^{\dagger, r} \subset \mathbf{B}_{K^{\prime}}^{\dagger, r}$ induce embeddings $\mathscr{E}^{\dagger}(K) \subset \mathscr{E}^{\dagger}\left(K^{\prime}\right)$ and $\mathscr{R}(K) \subset$ $\mathscr{R}\left(K^{\prime}\right)$. Let $t=\log (1+X)=\sum_{k=1}^{\infty}(-1)^{k+1} X^{k} / k \in \mathscr{R}\left(\mathbb{Q}_{p}\right)$. Note that $\varphi(t)=p t$ and $\tau(t)=\chi(\tau) t$ for all $\tau \in \Gamma_{K}$.

In this paper we deal with $p$-adic representations with coefficients in a finite extension $L$ of $\mathbb{Q}_{p}$. By this reason it is convenient to set $\mathscr{E}_{L}^{\dagger}(K)=\mathscr{E}^{\dagger}(K) \otimes_{\mathbb{Q}_{p}} L, \mathscr{R}_{L}^{\dagger}(K)=\mathscr{R}^{\dagger}(K) \otimes_{\mathbb{Q}_{p}} L$ and $\mathcal{O}_{\mathscr{E}_{L}^{\dagger}(K)}=$ $\mathcal{O}_{\mathscr{E}^{\dagger}(K)} \otimes_{\mathbb{Z}_{p}} O_{L}$.
Definition. i) $A\left(\varphi, \Gamma_{K}\right)$-module over $\mathscr{E}_{L}^{\dagger}(K)\left(\right.$ resp. $\mathscr{R}_{L}(K)$ ) is a free $\mathscr{E}_{L}^{\dagger}(K)$-module (resp. $\mathscr{R}_{L}(K)$ module) $\mathbf{D}$ of finite rank d equipped with semilinear actions of $\Gamma_{K}$ and $\varphi$ which commute to each other and such that the induced linear map $\mathscr{E}_{L}^{\dagger}(K) \otimes_{\varphi} \mathbf{D} \rightarrow \mathbf{D}$ (resp. $\mathscr{R}_{L}(K) \otimes_{\varphi} \mathbf{D} \rightarrow \mathbf{D}$ ) is an isomorphism.
ii) $A\left(\varphi, \Gamma_{K}\right)$-module $\mathbf{D}$ over $\mathscr{E}_{L}^{\dagger}(K)$ is said to be etale if there exists a basis of $\mathbf{D}$ such that the matrix of $\varphi$ in this basis is in $\mathrm{GL}_{d}\left(\mathcal{O}_{\mathscr{E}_{L}{ }^{\dagger}(K)}\right)$.

If $\mathbf{D}$ is a $\left(\varphi, \Gamma_{K}\right)$-module over $A=\mathscr{E}_{L}^{\dagger}(K)$ or $\mathscr{R}_{L}(K)$ we write $\mathbf{D}^{*}$ for the dual module $\operatorname{Hom}_{A}(\mathbf{D}, A)$ and $\mathbf{D}(\chi)$ for the module obtained from $\mathbf{D}$ by twisting the action of $\Gamma_{K}$ by the cyclotomic character.

Let $\operatorname{Rep}_{L}\left(G_{K}\right)$ be the category of $p$-adic representations of $G_{K}$ with coefficients in $L$ i.e. the category of finite dimensional $L$-vector spaces equipped with a continuous linear action of $G_{K}$.

Theorem 1.1.2 ([Fo1], [CC1]). There exists a natural functor $V \rightarrow \mathbf{D}^{\dagger}(V)$ which induces an equivalence between $\operatorname{Rep}_{L}\left(G_{K}\right)$ and the category of etale $\left(\varphi, \Gamma_{K}\right)$-modules over $\mathscr{E}_{L}^{\dagger}(K)$.

From Kedlaya's theory it follows [Cz5, Proposition 1.4 and Corollary 1.5] that the functor $\mathbf{D} \rightarrow$ $\mathscr{R}_{L}(K) \otimes_{\mathscr{E}_{L}^{\dagger}(K)} \mathbf{D}$ establishes an equivalence between the category of étale $\left(\varphi, \Gamma_{K}\right)$-modules over $\mathscr{E}_{L}^{\dagger}(K)$ and the category of $\left(\varphi, \Gamma_{K}\right)$-modules over $\mathscr{R}_{L}(K)$ of slope 0 in the sense of [Ke]. Together with Theorem 1.1.2 this implies that the functor $V \rightarrow \mathbf{D}_{\text {rig }}^{\dagger}(V)$ defined by $\mathbf{D}_{\text {rig }}^{\dagger}(V)=\mathscr{R}_{L}(K) \otimes_{\mathscr{E}_{L}^{\dagger}(K)} \mathbf{D}^{\dagger}(V)$ induces an equivalence between the category of $p$-adic representations and the category of $\left(\varphi, \Gamma_{K}\right)$-modules over $\mathscr{R}_{L}(K)$ of slope 0 .
1.1.3. Crystalline and semistable $\left(\varphi, \Gamma_{K}\right)$-modules (see [Fo3], [Ber3], [Ber4]). Recall that a filtered $(\varphi, N)$-module over $K$ with coefficients in $L$ is a free $K_{0} \otimes_{\mathbb{Q}_{p}} L$-vector space $M$ equipped with the following structures:

- a $\sigma$-semilinear isomorphism $\varphi: M \rightarrow M(\sigma$ acts trivially on $L)$;
- a $K_{0} \otimes \mathbb{Q}_{p} L$-linear nilpotent operator $N$ such that $N \varphi=p \varphi N$;
- an exhaustive decreasing filtration $\left(\mathrm{Fil}^{i} M_{K}\right)_{i \in \mathbb{Z}}$ on $M_{K}=K \otimes_{K_{0}} M$ by $\left(K \otimes_{\mathbb{Q}_{p}} L\right)$-submodules.

If $K^{\prime} / K$ is a finite Galois extension with Galois group $G_{K^{\prime} / K}$, then a filtered ( $\varphi, N, G_{K^{\prime} / K}$ )-module is a filtered $(\varphi, N)$-module $M$ over $K^{\prime}$ equipped with a semilinear action of $G_{K^{\prime} / K}$ such that the filtration Fil ${ }^{i} M_{K^{\prime}}$ is $G_{K^{\prime} / K^{\prime}}$-stable. We say that $M$ is a filtered $\left(\varphi, N, G_{K}\right)$-module if it is a filtered $\left(\varphi, N, G_{K^{\prime} / K}\right)$ module for some $K^{\prime} / K$. It is well known (see for example [Fo3]) that filtered ( $\varphi, N, G_{K}$ )-modules form a tensor category $\mathbf{M F}_{K}^{\varphi, N, G_{K}}$ which is additive, has kernels and cokernels but is not abelian. The unit object 1 of $\mathbf{M F}_{K}^{\varphi, N, G_{K}}$ is the module $K_{0} \otimes_{\mathbb{Q}_{p}} L$ with the natural action of $\varphi$ and the filtration given by

$$
\operatorname{Fil}^{i} \mathbf{1}_{K}= \begin{cases}K \otimes_{\mathbb{Q}_{p}} L, & \text { if } i \leqslant 0 \\ 0, & \text { if } i>0\end{cases}
$$

A filtered $(\varphi, N)$-module can be viewed as a filtered $\left(\varphi, N, G_{K}\right)$-module with the trivial action of $G_{K}$ and we denote by $\mathbf{M F}_{K}^{\varphi, N}$ the resulting subcategory. A filtered Dieudonné module is an object $M$ of $\mathbf{M F}_{K}^{\varphi, N}$ such that $N=0$ on $M$. Filtered Dieudonné modules form a full subcategory $\mathbf{M F}_{K}^{\varphi}$ of $\mathbf{M F}_{K}^{\varphi, N}$.

If $M$ is a filtered $\left(\varphi, N, G_{K}\right)$ - module of rank 1 and $m$ is a basis vector of $M$, then $\varphi(m)=\alpha m$ for some $\alpha \in L$. Set $t_{N}(M)=v_{p}(\alpha)$ and denote by $t_{H}(M)$ the unique jump in the filtration of $M$. If $M$ has rank $d \geqslant 1$, set $t_{N}(M)=t_{N}(\stackrel{d}{\wedge} M)$ and $t_{H}(M)=t_{H}(\stackrel{d}{\wedge} M)$. A filtered $\left(\varphi, N, G_{K}\right)$-module $M$ is said to be weakly admissible if $t_{H}(M)=t_{N}(M)$ and $t_{H}\left(M^{\prime}\right) \leqslant t_{N}\left(M^{\prime}\right)$ for any $\left(\varphi, N, G_{K}\right)$-submodule $M^{\prime}$ of $M$. Weakly admissible modules form a subcategory of $\mathbf{M F}_{K}^{\varphi, N, G_{K}}$ which we denote by $\mathbf{M F}_{K, f}^{\varphi, N, G_{K}}$.

Let $\mathscr{R}_{L, \log }(K)=\mathscr{R}_{L}(K)[\log X]$ where $\log X$ is transcendental over $\mathscr{R}_{L}(K)$ and

$$
\tau(\log X)=\log X+\log (\tau(X) / X), \quad \tau \in \Gamma_{K}, \quad \varphi(\log X)=p \log X+\log \left(\varphi(X) / X^{p}\right)
$$

Define a monodromy operator $N: \mathscr{R}_{L, \log }(K) \rightarrow \mathscr{R}_{L, \log }(K)$ by $N=-\left(1-\frac{1}{p}\right)^{-1} \frac{d}{d \log X}$. For any ( $\varphi, \Gamma_{K}$ )-module $\mathbf{D}$ over $\mathscr{R}_{L}(K)$ we set

$$
\mathscr{D}_{\text {cris }}(\mathbf{D})=\left(\mathbf{D} \otimes_{\mathscr{R}_{L}(K)} \mathscr{R}_{L}(K)[1 / t]\right)^{\Gamma_{K}}, \quad \mathscr{D}_{\text {st }}(\mathbf{D})=\left(\mathbf{D} \otimes_{\mathscr{R}_{L}(K)} \mathscr{R}_{L, \log }(K)[1 / t]\right)^{\Gamma_{K}} .
$$

Then $\mathscr{D}_{\text {cris }}(\mathbf{D})\left(\right.$ resp. $\left.\mathscr{D}_{\text {st }}(\mathbf{D})\right)$ is a $K \otimes_{\mathbb{Q}_{p}} L$-module of finite rank equipped with a natural action of $\varphi$ (resp. with natural actions of $\varphi$ and $N$ ). There exists a compatible system of embeddings $\varphi^{-m}$ : $\left.\mathscr{R}_{L}(K)^{(r)} \rightarrow\left(L \otimes K_{\infty}\right)[t t]\right]$ which allows to define exhaustive decreasing filtrations on $\mathscr{D}_{\text {cris }}(\mathbf{D})_{K}$ and $\left.\mathscr{D}_{\text {st }}(\mathbf{D})_{K}\right)\left(\right.$ see [Ber4, proof of Theorem III.2.3] ). Moreover $\mathscr{D}_{\text {cris }}(\mathbf{D})=\mathscr{D}_{\text {st }}(\mathbf{D})^{N=0}$ and

$$
\operatorname{rg}\left(\mathscr{D}_{\text {cris }}(\mathbf{D})\right) \leqslant \operatorname{rg}\left(\mathscr{D}_{\text {st }}(\mathbf{D})\right) \leqslant \operatorname{rg}(\mathbf{D})
$$

We say that $\mathbf{D}$ is crystalline (resp. semistable) if $\operatorname{rg}\left(\mathscr{D}_{\text {cris }}(\mathbf{D})\right)=\operatorname{rg}(\mathbf{D})\left(\right.$ resp. $\left.\operatorname{rg}\left(\mathscr{D}_{\mathrm{st}}(\mathbf{D})\right)=\operatorname{rg}(\mathbf{D})\right)$.
If $K^{\prime} / K$ is a finite extention, then $\mathscr{R}_{L}(K) \subset \mathscr{R}_{L}\left(K^{\prime}\right)$ and we set $\mathbf{D}_{K^{\prime}}=\mathscr{R}_{L}\left(K^{\prime}\right) \otimes_{\mathscr{R}_{L}(K)} \mathbf{D}$. The projective limit

$$
\mathscr{D}_{\mathrm{pst}}(\mathbf{D})=\varliminf_{K^{\prime} / K} \mathscr{D}_{\mathrm{st} / K^{\prime}}\left(\mathbf{D}_{K^{\prime}}\right)
$$

is a $K_{0}^{u r} \otimes_{\mathbb{Q}_{p}} L$-module of finite rank equipped with a discrete action of $G_{K}$ and we say that $\mathbf{D}$ is potentially semistable if $\operatorname{rg}\left(\mathscr{D}_{\text {pst }}(\mathbf{D})\right)=\operatorname{rg}(\mathbf{D})$. Denote by $\mathbf{M}_{\mathrm{pst}, K}^{\varphi, \Gamma},{ }_{\mathbf{M}}^{\mathrm{st}, K},{ }^{\varphi, \Gamma}$ and $\mathbf{M}_{\text {cris }, K}^{\varphi, \Gamma}$ the categories of potentially semistable, semistable and crystalline ( $\varphi, \Gamma_{K}$ )-modules respectively.

Proposition 1.1.4. i) The functors $\mathscr{D}_{\text {cris }}: \mathbf{M}_{\text {cris }, K}^{\varphi, \Gamma} \rightarrow \mathbf{M F}_{K}^{\varphi}, \mathscr{D}_{\text {st }}: \mathbf{M}_{\mathrm{st}, K}^{\varphi, \Gamma} \rightarrow \mathbf{M F}_{K}^{\varphi, N}$ and $\mathscr{D}_{\text {pst }}$ : $\mathbf{M}_{\mathrm{pst}, K}^{\varphi, \Gamma} \rightarrow \mathbf{M F}_{K}^{\varphi, N, G_{K}}$ are equivalences of categories.
ii) If $V$ is a p-adic representation of $G_{K}$ then $\mathscr{D}_{\text {cris }}\left(\mathbf{D}_{\text {rig }}^{\dagger}(V)\right)\left(\right.$ resp. $\mathscr{D}_{\text {st }}\left(\mathbf{D}_{\text {rig }}^{\dagger}(V)\right)$, resp. $\left.\mathscr{D}_{\text {pst }}\left(\mathbf{D}_{\text {rig }}^{\dagger}(V)\right)\right)$ is canonically and fonctorially isomorphic to Fontaine's module $\mathbf{D}_{\text {cris }}(V)$ (resp. $\mathbf{D}_{\text {st }}(V)$, resp. $\mathbf{D}_{\mathrm{pst}}(V)$ ).

Proof. The first statement is the main result of [Ber4]. The second statement follows from [Ber1, Theorem 0.2].

### 1.2. Cohomology of $(\varphi, \Gamma)$-modules.

1.2.1. Fontaine-Herr complexes (see [H1], [H2], [Liu]). Let $A$ be either $\mathscr{E}_{L}^{\dagger}(K)$ or $\mathscr{R}_{L}(K)$. We fix a generator $\gamma_{K} \in \Gamma_{K}$. If $\mathbf{D}$ is a $\left(\varphi, \Gamma_{K}\right)$-module over $A$ we shall write $H^{*}(\mathbf{D})$ for the cohomology of the complex

$$
C_{\varphi, \gamma_{K}}(\mathbf{D}): 0 \rightarrow \mathbf{D} \xrightarrow{f} \mathbf{D} \oplus \mathbf{D} \xrightarrow{g} \mathbf{D} \rightarrow 0
$$

where $f(x)=\left((\varphi-1) x,\left(\gamma_{K}-1\right) x\right)$ and $g(y, z)=\left(\gamma_{K}-1\right) y-(\varphi-1) z$. A short exact sequence of $\left(\varphi, \Gamma_{K}\right)$-modules

$$
0 \rightarrow \mathbf{D}^{\prime} \rightarrow \mathbf{D} \rightarrow \mathbf{D}^{\prime \prime} \rightarrow 0
$$

gives rise to an exact cohomology sequence:

$$
0 \rightarrow H^{0}\left(\mathbf{D}^{\prime}\right) \rightarrow H^{0}(\mathbf{D}) \rightarrow H^{0}\left(\mathbf{D}^{\prime \prime}\right) \rightarrow H^{1}\left(\mathbf{D}^{\prime}\right) \rightarrow \cdots \rightarrow H^{2}\left(\mathbf{D}^{\prime \prime}\right) \rightarrow 0
$$

The cohomology of $\left(\varphi, \Gamma_{K}\right)$-modules over $\mathscr{R}_{L}(K)$ satisfies the following fondamental properties (see [Liu, Theorem 0.2]):

- Euler characteristic formula. $H^{*}(\mathbf{D})$ are finite dimensional $L$-vector spaces and the usual formula for the Euler characteristic holds

$$
\sum_{i=0}^{2}(-1)^{i} \operatorname{dim}_{L} H^{i}(\mathbf{D})=-\left[K: \mathbb{Q}_{p}\right] \operatorname{rg}_{\mathscr{R}_{L}(K)}(\mathbf{D}) .
$$

- Poincaré duality. For each $i=0,1,2$ there exist functorial pairings

$$
H^{i}(\mathbf{D}) \times H^{2-i}\left(\mathbf{D}^{*}(\chi)\right) \xrightarrow{\cup} H^{2}\left(\mathscr{R}_{L}(K)(\chi)\right) \simeq L
$$

which are compatible with the connecting homomorphisms in the usual sense.

Proposition 1.2.2. Let $V$ be a p-adic representation of $G_{K}$. Then
i) The continuous Galois cohomology $H^{*}(K, V)$ is canonically (up to the choice of $\gamma_{K}$ ) and functorially isomorphic to $H^{*}\left(\mathbf{D}^{\dagger}(V)\right)$.
ii) The natural map $\mathbf{D}^{\dagger}(V) \rightarrow \mathbf{D}_{\text {rig }}^{\dagger}(V)$ induces a quasi-isomorphism of complexes $C_{\varphi, \gamma_{K}}\left(\mathbf{D}^{\dagger}(V)\right) \rightarrow$ $C_{\varphi, \gamma_{K}}\left(\mathbf{D}_{\text {rig }}^{\dagger}(V)\right)$.
Proof. See [H1] and [Liu, Theorem 1.1].
1.2.3. Iwasawa cohomology (see [CC2]). If $V$ is a $p$-adic representation of $G_{K}$ and $T$ is an $O_{L}$-lattice of $V$ stable under $G_{K}$ we define
and $H_{\mathrm{Iw}}^{i}(K, V)=H_{\mathrm{Iw}}^{i}(K, T) \otimes_{O_{L}} L$. Since $\mathbf{D}^{\dagger}(V)$ is etale, each $x \in \mathbf{D}^{\dagger}(V)$ can be written in the form $x=\sum_{i=1}^{d} a_{i} \varphi\left(e_{i}\right)$ where $\left\{e_{i}\right\}_{i=1}^{d}$ is a basis of $\mathbf{D}^{\dagger}(V)$ and $a_{i} \in \mathscr{E}_{L}^{\dagger}(K)$. Therefore the formula

$$
\psi\left(\sum_{i=1}^{d} a_{i} \varphi\left(e_{i}\right)\right)=\sum_{i=1}^{d} \psi\left(a_{i}\right) e_{i}
$$

defines an operator $\psi: \mathbf{D}^{\dagger}(V) \rightarrow \mathbf{D}^{\dagger}(V)$ which is a left inverse for $\varphi$. The Iwasawa cohomology $H_{\mathrm{Iw}}^{*}(K, V)$ is canonically (up to the choice of $\gamma_{K}$ ) and functorially isomorphic to the cohomology of the complex

$$
C_{\mathrm{Iw}, \psi}^{\dagger}(V): \mathbf{D}^{\dagger}(V) \xrightarrow{\psi-1} \mathbf{D}^{\dagger}(V) .
$$

The projection map $\operatorname{pr}_{V, n}: H_{\mathrm{Iw}}^{1}(K, V) \rightarrow H^{1}\left(K_{n}, V\right)$ has the following explicit description. Set $\gamma_{K, n}=$ $\gamma_{K}^{\left[K_{n}: K\right]}$. Let $x \in \mathbf{D}^{\dagger}(V)^{\psi=1}$. Then $(\varphi-1) x \in \mathbf{D}^{\dagger}(V)^{\psi=0}$ and by [CC1, Lemma 1.5.1] there exists $y \in \mathbf{D}^{\dagger}(V)$ such that $\left(\gamma_{K, n}-1\right) y=(\varphi-1) x$. Then $\operatorname{pr}_{V, n}$ sends $x$ to $\operatorname{cl}(y, x)$. This interpretation of the Iwasawa cohomology was found by Fontaine (unpublished but see [CC2]).
1.2.4. The exponential map (see $[\mathrm{BK}],[\mathrm{Ne}],[\mathrm{Ben} 2])$. Let $\mathbf{D}$ be a $\left(\varphi, \Gamma_{K}\right)$-module. To any cocycle $\alpha=(a, b) \in Z^{1}\left(C_{\varphi, \gamma}(\mathbf{D})\right)$ one can associate the extension

$$
0 \rightarrow \mathbf{D} \rightarrow \mathbf{D}_{\alpha} \rightarrow \mathscr{R}_{L}(K) \rightarrow 0
$$

defined by

$$
\mathbf{D}_{\alpha}=\mathbf{D} \oplus \mathscr{R}_{L}(K) e, \quad(\varphi-1) e=a, \quad\left(\gamma_{K}-1\right) e=b
$$

As usual, this gives rise to a canonical isomorphism $H^{1}(\mathbf{D}) \simeq \operatorname{Ext}_{\left(\varphi, \Gamma_{K}\right)}^{1}\left(\mathscr{R}_{L}(K), \mathbf{D}\right)$. We say that the class cl $(\alpha)$ of $\alpha$ in $H^{1}(\mathbf{D})$ is crystalline if $\operatorname{rg}_{L \otimes K_{0}} \mathscr{D}_{\text {cris }}\left(\mathbf{D}_{\alpha}\right)=\operatorname{rg}_{L \otimes K_{0}} \mathscr{D}_{\text {cris }}(\mathbf{D})+1$ and define

$$
H_{f}^{1}(\mathbf{D})=\left\{\operatorname{cl}(\alpha) \in H^{1}(\mathbf{D}) \mid \operatorname{cl}(\alpha) \text { is crystalline }\right\}
$$

(see [Ben2, Section 1.4]). Now assume that $\mathbf{D}$ is potentially semistable and define the tangent space of D as

$$
t_{\mathbf{D}}(K)=\mathscr{D}_{\mathrm{dR}}(\mathbf{D}) / \mathrm{Fil}^{0} \mathscr{D}_{\mathrm{dR}}(\mathbf{D}) .
$$

Consider the complex

$$
C_{\text {cris }}^{\bullet}(\mathbf{D}): \mathscr{D}_{\text {cris }}(\mathbf{D}) \xrightarrow{f} t_{\mathbf{D}}(K) \oplus \mathscr{D}_{\text {cris }}(\mathbf{D})
$$

where the modules are placed in degrees 0 and 1 and $f(d)=\left(d\left(\bmod \operatorname{Fil}^{0} \mathscr{D}_{\mathrm{dR}}(\mathbf{D})\right),(1-\varphi)(d)\right)($ see [Ne], [FP]). From Proposition 1.1.4 it follows the existence of a canonical isomorphism

$$
H^{1}\left(C_{\text {cris }}^{\bullet}(\mathbf{D})\right) \rightarrow H_{f}^{1}(\mathbf{D})
$$

(see [Ben2, Proposition 1.4.4] for the proof). We define the exponential map

$$
\exp _{\mathbf{D}, K}: t_{\mathbf{D}}(K) \oplus \mathscr{D}_{\text {cris }}(\mathbf{D}) \rightarrow H^{1}(\mathbf{D})
$$

as the composition of this isomorphism with the natural projection $t_{\mathbf{D}}(K) \oplus \mathscr{D}_{\text {cris }}(\mathbf{D}) \rightarrow H^{1}\left(C_{\text {cris }}^{\bullet}(\mathbf{D})\right)$ and the embedding $H_{f}^{1}(\mathbf{D}) \hookrightarrow H^{1}(\mathbf{D})$.

If $V$ is a potentially semistable representation and $\mathbf{D}=\mathbf{D}_{\mathrm{rig}}^{\dagger}(V)$ then the isomorphism $H^{1}(\mathbf{D}) \simeq$ $H^{1}(K, V)$ identifies $H_{f}^{1}(\mathbf{D})$ with $H_{f}^{1}(K, V)$ of Bloch-Kato [Ben2, Proposition 1.4.2]. Let

$$
t_{V}(K)=\mathbf{D}_{\mathrm{dR}}(V) / \operatorname{Fil}^{0} \mathbf{D}_{\mathrm{dR}}(V)
$$

denote the tangent space of $V$. By [Ne, Proposition 1.21] the following diagram commutes and identifies our exponential map with the exponential map $\exp _{V, K}$ of Bloch-Kato [BK, §4]

Let

$$
[,]: \mathscr{D}_{\mathrm{dR}}(\mathbf{D}) \times \mathscr{D}_{\mathrm{dR}}\left(\mathbf{D}^{*}(\chi)\right) \rightarrow L \otimes_{\mathbb{Q}_{p}} K
$$

be the canonical duality. The dual exponential map

$$
\exp _{\mathbf{D}^{*}(\chi), K}^{*}: H^{1}\left(\mathbf{D}^{*}(\chi)\right) \rightarrow \operatorname{Fil}^{0} \mathscr{D}_{\mathrm{dR}}\left(\mathbf{D}^{*}(\chi)\right)
$$

is defined to be the unique linear map such that

$$
\exp _{\mathbf{D}, K}(x) \cup y=\operatorname{Tr}_{K / \mathbb{Q}_{p}}\left[x, \exp _{\mathbf{D}^{*}(\chi), K}^{*}(y)\right]
$$

for all $x \in \mathscr{D}_{\mathrm{dR}}(\mathbf{D}), y \in \mathscr{D}_{\mathrm{dR}}\left(\mathbf{D}^{*}(\chi)\right)$.
1.2.5. $(\varphi, \Gamma)$-modules of rank 1 (see [Cz5], [Ben2]). In this paper we deal with potentially semistable representations of $G_{\mathbb{Q}_{p}}$. To simplify notation we set $K_{n}=\mathbb{Q}_{p}\left(\zeta_{p^{n}}\right), \mathscr{E}_{L}^{\dagger}=\mathscr{E}_{L}^{\dagger}\left(\mathbb{Q}_{p}\right), \mathscr{R}_{L}=\mathscr{R}_{L}\left(\mathbb{Q}_{p}\right)$, $\Gamma=\Gamma_{\mathbb{Q}_{p}}$ and we fix a topological generator $\gamma$ of $\Gamma$. With each continuous character $\delta: \mathbb{Q}_{p}^{*} \rightarrow L^{*}$ one can associate the $(\varphi, \Gamma)$-module of rank one $\mathscr{R}_{L}(\delta)=\mathscr{R}_{L} e_{\delta}$ defined by $\gamma\left(e_{\delta}\right)=\delta(\chi(\gamma)) e_{\delta}$ and $\varphi\left(e_{\delta}\right)=\delta(p) e_{\delta}$. Colmez proved that any $(\varphi, \Gamma)$-module of rank one over $\mathscr{R}_{L}$ is isomorphic to one and only one of $\mathscr{R}_{L}(\delta)$ [Cz5, Proposition 3.1]. It is easy to see that $\mathscr{R}_{L}(\delta)$ is crystalline if and only if there exists $m \in \mathbb{Z}$ such that $\delta(u)=u^{m}$ for all $u \in \mathbb{Z}_{p}^{*}$ [Ben2, Lemma 1.5.2]. In this case $\mathscr{D}_{\text {cris }}\left(\mathscr{R}_{L}(\delta)\right)$ is the one-dimensional vector space generated by $t^{-m} e_{\delta}$ with Hodge-Tate weight equal to $-m$ and $\varphi$ acts on $\mathscr{D}_{\text {cris }}\left(\mathscr{R}_{L}(\delta)\right)$ as multiplication by $p^{-m} \delta(p)$. The computation of the cohomology of crystalline $(\varphi, \Gamma)$-modules of rank 1 reduces to the following four cases. We refer to [Cz5, Sections 2.3-2.5] and to [Ben2, Proposition 1.5.3 and Theorem 1.5.7] for proofs and more details.

- $\delta(u)=u^{-m}\left(u \in \mathbb{Z}_{p}^{*}\right)$ for some $m \geqslant 0$ but $\delta(x) \neq x^{-m}$. In this case $H^{i}\left(\mathscr{R}_{L}(\delta)\right)=0$ for $i=0,2$, $H^{1}\left(\mathscr{R}_{L}(\delta)\right)$ is a one-dimensional $L$-vector space and $H_{f}^{1}\left(\mathscr{R}_{L}(\delta)\right)=0$.
- $\delta(x)=x^{-m}$ for some $m \geqslant 0$. In this case $H^{0}\left(\mathscr{R}_{L}(\delta)\right)=\mathscr{D}_{\text {cris }}\left(\mathscr{R}_{L}(\delta)\right)$ and $H^{2}\left(\mathscr{R}_{L}(\delta)\right)=0$. The map

$$
\begin{aligned}
& i_{\delta}: \mathscr{D}_{\text {cris }}\left(\mathscr{R}_{L}(\delta)\right) \oplus \mathscr{D}_{\text {cris }}\left(\mathscr{R}_{L}(\delta)\right) \rightarrow H^{1}\left(\mathscr{R}_{L}(\delta)\right) \\
& i_{\delta}(x, y)=\operatorname{cl}(-x, \log \chi(\gamma) y)
\end{aligned}
$$

is an isomorphism. We let $i_{\delta, f}$ and $i_{\delta, c}$ denote its restrictions on the first and second direct summand respectively. Then $\operatorname{Im}\left(i_{\delta, f}\right)=H_{f}^{1}\left(\mathscr{R}_{L}(\delta)\right)$ and we have a canonical decomposition

$$
\begin{equation*}
H^{1}\left(\mathscr{R}_{L}(\delta)\right) \simeq H_{f}^{1}\left(\mathscr{R}_{L}(\delta)\right) \oplus H_{c}^{1}\left(\mathscr{R}_{L}(\delta)\right) \tag{5}
\end{equation*}
$$

where $H_{c}^{1}\left(\mathscr{R}_{L}(\delta)\right)=\operatorname{Im}\left(i_{\delta, c}\right)$. Set

$$
\begin{aligned}
& \mathbf{x}_{m}=i_{\delta, f}\left(t^{m} e_{\delta}\right)=-\operatorname{cl}\left(t^{m}, 0\right) e_{\delta}, \\
& \mathbf{y}_{m}=i_{\delta, c}\left(t^{m} e_{\delta}\right)=\log \chi(\gamma) \operatorname{cl}\left(0, t^{m}\right) e_{\delta}
\end{aligned}
$$

- $\delta(u)=u^{m}\left(u \in \mathbb{Z}_{p}^{*}\right)$ for some $m \geqslant 1$ but $\delta(x) \neq|x| x^{m}$. Then $H^{i}\left(\mathscr{R}_{L}(\delta)\right)=0$ for $i=0,2, H^{1}\left(\mathscr{R}_{L}(\delta)\right)$ is a one-dimensional $L$-vector space and $H_{f}^{1}\left(\mathscr{R}_{L}(\delta)\right)=H^{1}\left(\mathscr{R}_{L}(\delta)\right)$.
- $\delta(x)=|x| x^{m}$ for some $m \geqslant 1$. Then $H^{0}\left(\mathscr{R}_{L}(\delta)\right)=0$ and $H^{2}\left(\mathscr{R}_{L}(\delta)\right)$ is a one-dimensional $L$-vector space. Moreover $\chi \delta^{-1}(x)=x^{1-m}$ and there exists a unique isomorphism

$$
i_{\delta}: \mathscr{D}_{\text {cris }}\left(\mathscr{R}_{L}(\delta)\right) \oplus \mathscr{D}_{\text {cris }}\left(\mathscr{R}_{L}(\delta)\right) \rightarrow H^{1}\left(\mathscr{R}_{L}(\delta)\right)
$$

such that

$$
i_{\delta}(\alpha, \beta) \cup i_{\chi \delta^{-1}}(x, y)=[\beta, x]-[\alpha, y]
$$

where [, ] : $\mathscr{D}_{\text {cris }}\left(\mathscr{R}_{L}(\delta)\right) \times \mathscr{D}_{\text {cris }}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right) \rightarrow L$ is the canonical pairing. Denote $i_{\delta, f}$ and $i_{\delta, c}$ the restrictions of $i_{\delta}$ on the first and second direct summand respectively. Then $\operatorname{Im}\left(i_{\delta, f}\right)=H_{f}^{1}\left(\mathscr{R}_{L}(\delta)\right)$ and again we have a canonical decomposition

$$
\begin{equation*}
H^{1}\left(\mathscr{R}_{L}(\delta)\right) \simeq H_{f}^{1}\left(\mathscr{R}_{L}(\delta)\right) \oplus H_{c}^{1}\left(\mathscr{R}_{L}(\delta)\right) \tag{6}
\end{equation*}
$$

where $H_{c}^{1}\left(\mathscr{R}_{L}(\delta)\right)=\operatorname{Im}\left(i_{\delta, c}\right)$.
More explicitly, let $\boldsymbol{\alpha}_{m}=-\left(1-\frac{1}{p}\right) \operatorname{cl}\left(\alpha_{m}\right)$ and $\boldsymbol{\beta}_{m}=\left(1-\frac{1}{p}\right) \log \chi(\gamma) \operatorname{cl}\left(\beta_{m}\right)$ where

$$
\begin{aligned}
& \alpha_{m}=\frac{(-1)^{m-1}}{(m-1)!} \partial^{m-1}\left(\frac{1}{X}+\frac{1}{2}, a\right) e_{\delta}, \quad(1-\varphi) a=(1-\chi(\gamma) \gamma)\left(\frac{1}{X}+\frac{1}{2}\right), \\
& \beta_{m}=\frac{(-1)^{m-1}}{(m-1)!} \partial^{m-1}\left(b, \frac{1}{X}\right) e_{\delta}, \quad(1-\varphi)\left(\frac{1}{X}\right)=(1-\chi(\gamma) \gamma) b
\end{aligned}
$$

and $\partial=(1+X) \frac{d}{d X}$. Then $H_{f}^{1}\left(\mathscr{R}_{L}(\delta)\right)$ and $H_{c}^{1}\left(\mathscr{R}_{L}(\delta)\right)$ are generated by $\boldsymbol{\alpha}_{m}$ and $\boldsymbol{\beta}_{m}$ respectively and one has

$$
\begin{equation*}
\boldsymbol{\alpha}_{m} \cup \mathbf{x}_{m-1}=\boldsymbol{\beta}_{m} \cup \mathbf{y}_{m-1}=0, \quad \boldsymbol{\alpha}_{m} \cup \mathbf{y}_{m-1}=-1, \quad \boldsymbol{\beta}_{m} \cup \mathbf{x}_{m-1}=1 \tag{7}
\end{equation*}
$$

Proposition 1.2.6. Let $\delta(x)=|x| x^{m}$ where $m \geqslant 1$. Then $d_{m}=t^{-m} e_{\delta}$ is a basis of $\mathscr{D}_{\text {cris }}\left(\mathscr{R}_{L}(\delta)\right)$ and the exponential map sends $\left(d_{m}, 0\right)$ to $\boldsymbol{\alpha}_{m}$.

Proof. See [Ben2, Theorem 1.5.7].

### 1.3. The large exponential map.

1.3.1. The large exponential map (see [PR2], [Cz1], [Ben1], [Ber2]). In this section we review the construction and basic properties of Perrin-Riou's large exponential map [PR2]. We work with $p$-adic representations of $G_{\mathbb{Q}_{p}}$ and keep notations of Section 1.2.5. Let $p$ be an odd prime number. We let denote $\Lambda=O_{L}[[\Gamma]]$ the Iwasawa algebra of $\Gamma$ over $O_{L}$ and set $\mathscr{R}_{L}^{+}=\mathscr{R}_{L} \cap L[[X]]$. We remark that $\mathscr{R}_{L}^{+}$ is the ring of power series with coefficients in $L$ which converge on the open unit disk. Fix a topological generator $\gamma$ of $\Gamma$ and define a compartible system of generators of $\Gamma_{n}$ setting $\gamma_{1}=\gamma^{p-1}$ and $\gamma_{n+1}=\gamma_{n}^{p}$ for $n \geqslant 1$. Let $\Delta=\operatorname{Gal}\left(K_{1} / \mathbb{Q}_{p}\right)$. Define

$$
\mathscr{H}=\left\{f\left(\gamma_{1}-1\right) \mid f \in \mathscr{R}_{L}^{+}\right\}, \quad \mathscr{H}(\Gamma)=\mathbb{Z}_{p}[\Delta] \otimes_{\mathbb{Z}_{p}} \mathscr{H}(\Gamma) .
$$

Thus $\mathscr{H}(\Gamma)=\underset{i=0}{p-2} \mathscr{H} \delta_{i}$ where $\delta_{i}=\frac{1}{|\Delta|} \sum_{g \in \Delta} \omega^{-i}(g) g$. We equip $\mathscr{H}(\Gamma)$ with twist operators $\mathrm{Tw}_{m}$ : $\mathscr{H}(\Gamma) \rightarrow \mathscr{H}(\Gamma)$ defined by $\operatorname{Tw}_{m}\left(f\left(\gamma_{1}-1\right) \delta_{i}\right)=f\left(\chi\left(\gamma_{1}\right)^{m} \gamma_{1}-1\right) \delta_{i-m}$. The ring $\mathscr{H}(\Gamma)$ acts on $\mathscr{R}_{L}^{+}$and $\left(\mathscr{R}_{L}^{+}\right)^{\psi=0}$ is the free $\mathscr{H}(\Gamma)$-module generated by $(1+X)$ [PR2, Proposition 1.2.7].

Let $V$ be a potentially semistable representation of $G_{\mathbb{Q}_{p}}$. Set $\mathcal{D}(V)=\left(\mathscr{R}_{L}^{+}\right)^{\psi=0} \otimes_{L} \mathbf{D}_{\text {cris }}(V)$ and define a map

$$
\Xi_{V, n}^{\varepsilon}: \mathcal{D}(V) \rightarrow H^{1}\left(K_{n}, C_{\text {cris }}^{\bullet}\left(\mathbf{D}_{\text {rig }}^{\dagger}(V)\right)\right)=\operatorname{coker}\left(\mathbf{D}_{\text {cris }}(V) \xrightarrow{f} t_{V}\left(K_{n}\right) \oplus \mathbf{D}_{\text {cris }}(V)\right)
$$

by

$$
\Xi_{V, n}^{\varepsilon}(\alpha)= \begin{cases}p^{-n}\left(\sum_{k=1}^{n}(\sigma \otimes \varphi)^{-k} \alpha\left(\zeta_{p^{k}}-1\right),-\alpha(0)\right) & \text { if } n \geqslant 1, \\ -\left(0,\left(1-p^{-1} \varphi^{-1}\right) \alpha(0)\right) & \text { if } n=0 .\end{cases}
$$

In particular, if $\mathbf{D}_{\text {cris }}(V)^{\varphi=1}=0$ the operator $1-\varphi$ is invertible on $\mathbf{D}_{\text {cris }}(V)$ and

$$
\Xi_{V, 0}^{\varepsilon}(\alpha)=\left(\frac{1-p^{-1} \varphi^{-1}}{1-\varphi} \alpha(0), 0\right)
$$

For any $m \in \mathbb{Z}$ let $\mathrm{Tw}_{V, m}^{\varepsilon}: H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, V\right) \rightarrow H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, V(m)\right)$ denote the twist map $\mathrm{Tw}_{V, m}^{\varepsilon}(x)=x \otimes \varepsilon^{\otimes m}$.
Theorem 1.3.2. Let $V$ be a potentially semistable representation of $G_{\mathbb{Q}_{p}}$ such that $H^{0}\left(K_{\infty}, V\right)=0$. Then for any integers $h$ and $m$ such that $\operatorname{Fil}^{-h} \mathbf{D}_{\mathrm{dR}}(V)=\mathbf{D}_{\mathrm{dR}}(V)$ and $m+h \geqslant 1$ there exists a unique $\mathscr{H}(\Gamma)$-homomorphism

$$
\operatorname{Exp}_{V(m), h}^{\varepsilon}: \mathcal{D}(V(m)) \rightarrow \mathscr{H}(\Gamma) \otimes_{\Lambda_{\mathbb{Q}_{p}}} H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, V(m)\right)
$$

satisfying the following properties:

1) For any $n \geqslant 0$ the diagram

$$
\begin{array}{ccc}
\mathcal{D}(V(m)) & \xrightarrow{\operatorname{Expe}_{V(m), h}^{\varepsilon}} \quad \mathscr{H}(\Gamma) \otimes_{\Lambda_{Q_{p}}} H_{\mathrm{IW}}^{1}\left(\mathbb{Q}_{p}, V(m)\right) \\
\Xi_{V(m), n}^{\varepsilon} \downarrow & { }^{\operatorname{pr}_{V(m), n}} \downarrow \\
H^{1}\left(K_{n}, C_{\mathrm{cris}}^{\bullet}\left(\mathbf{D}_{\mathrm{rig}}^{\dagger}(V(m))\right) \xrightarrow{(h-1)!\exp _{V(m), K_{n}}}\right. & H^{1}\left(K_{n}, V(m)\right)
\end{array}
$$

commutes.
ii) Let $e_{1}=\varepsilon^{-1} \otimes t$ denote the canonical generator of $\mathbf{D}_{\text {cris }}\left(\mathbb{Q}_{p}(-1)\right)$. Then

$$
\operatorname{Exp}_{V(m+1), h+1}^{\varepsilon}=-\mathrm{Tw}_{V(m), 1}^{\varepsilon} \circ \operatorname{Exp}_{V(m), h}^{\varepsilon} \circ\left(\partial \otimes e_{1}\right)
$$

iii) One has

$$
\operatorname{Exp}_{V(m), h+1}^{\varepsilon}=\ell_{h} \operatorname{Exp}_{V(m), h}^{\varepsilon}
$$

where $\ell_{m}=m-\frac{\log \left(\gamma_{1}\right)}{\log \chi\left(\gamma_{1}\right)}$.
Proof. This theorem was first proved in [PR2] for crystalline representations. Other proofs can be found in [Cz1], [KKT], [Ben1] and [Ber2]. Note that in [Cz1] and [KKT] $V$ is not assumed to be crystalline. We also remark that in $[\mathrm{PR} 2] \operatorname{Exp}_{V, h}^{\varepsilon}(\alpha)$ was defined only for $\alpha$ such that $\partial^{m} \alpha(0) \in\left(1-p^{m} \varphi\right) \mathbf{D}_{\text {cris }}(V)$ for all $m \in \mathbb{Z}$. This condition is not necessary (see [PR4] or [Ben1, Section 5.1]).

We recall now the construction of $\operatorname{Exp}_{V, h}^{\varepsilon}$ in terms of $(\varphi, \Gamma)$-modules found by Berger. This construction will be used in the proof of Proposition 2.2 .2 below. Again in [Ber2], Berger assumes that $V$ is crystalline, but his arguments work in the potentially semistable case. We refer to [Pt] for more detail. The action of $\mathscr{H}(\Gamma)$ on $\mathbf{D}^{\dagger}(V)^{\psi=1}$ induces an isomorphism $\mathscr{H}(\Gamma) \otimes_{\Lambda_{Q_{p}}} \mathbf{D}^{\dagger}(V)^{\psi=1} \rightarrow \mathbf{D}_{\text {rig }}^{\dagger}(V)^{\psi=1}$ (see [Pt, Section 6.4]). Composing this map with the canonical isomorphism $H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, V\right) \simeq \mathbf{D}^{\dagger}(V)^{\psi=1}$ we obtain an isomorphism $\mathscr{H}(\Gamma) \otimes_{\Lambda_{\mathbb{Q}_{p}}} H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, V\right) \rightarrow \mathbf{D}_{\text {rig }}^{\dagger}(V)^{\psi=1}$. It is not difficult to check that $\ell_{m}$ acts on $\mathscr{R}_{L}$ as $m-t \partial$ and an easy induction shows that $\prod_{k=0}^{h-1} \ell_{k}=(-1)^{h} t^{h} \partial^{h}$. Let $h \geqslant 1$ be such that Fil ${ }^{-h} \mathbf{D}_{\mathrm{dR}}(V)=\mathbf{D}_{\mathrm{dR}}(V)$. To simplify the formulation, assume that $\mathbf{D}_{\text {cris }}(V)^{\varphi=1}=0$. For any $\alpha \in \mathcal{D}(V)$ the equation

$$
(\varphi-1) F=\alpha-\sum_{m=1}^{h} \frac{\partial^{m} \alpha(0)}{m!} t^{m}
$$

has a solution in $\mathscr{R}_{L}^{+} \otimes \mathbf{D}_{\text {cris }}(V)$ and we define

$$
\Omega_{V, h}^{\varepsilon}(\alpha)=\frac{\log \chi\left(\gamma_{1}\right)}{p} \ell_{h-1} \ell_{h-2} \cdots \ell_{0}(F(X))
$$

It is easy to see that $\Omega_{V, h}^{\varepsilon}(\alpha) \in \mathbf{D}_{\text {rig }}^{+}(V)^{\psi=1}$ and in [Ber2, Theorem II.13] Berger shows that $\Omega_{V, h}^{\varepsilon}(\alpha)$ coincides with $\operatorname{Exp}_{V, h}^{\varepsilon}(\alpha)$.
1.3.3. The logarithmic maps. The Iwasawa algebra $\Lambda$ is equipped with an involution $\iota: \Lambda \rightarrow \Lambda$ defined by $\iota(\tau)=\tau^{-1}, \tau \in \Gamma$. If $M$ is a $\Lambda$-module we set $M^{\iota}=\Lambda \otimes_{\iota} M$ and denote by $m \mapsto m^{\iota}$ the canonical bijection of $M$ onto $M^{\iota}$. Thus $\lambda m^{\iota}=(\iota(\lambda) m)^{\iota}$ for all $\lambda \in \Lambda, m \in M$. Let $T$ be a $O_{L}$-lattice of $V$ stable under the action of $G_{\mathbb{Q}_{p}}$. The cohomological pairings

$$
(,)_{T, n}: H^{1}\left(K_{n}, T\right) \times H^{1}\left(K_{n}, T^{*}(1)\right) \rightarrow O_{L}
$$

give rise to a $\Lambda$-bilinear pairing

$$
\langle,\rangle_{T}: H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, T\right) \times H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, T^{*}(1)\right)^{\iota} \rightarrow \Lambda
$$

defined by

$$
\left\langle x, y^{\iota}\right\rangle_{T} \equiv \sum_{\tau \in \Gamma / \Gamma_{n}}\left(\tau^{-1} x_{n}, y_{n}\right)_{T, n} \tau \bmod \left(\gamma_{n}-1\right), \quad n \geqslant 1
$$

(see [PR2, Section 3.6.1]). By linearity we extend this pairing to

$$
\langle,\rangle_{V}: \mathscr{H}(\Gamma) \otimes_{\Lambda} H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, T\right) \times \mathscr{H}(\Gamma) \otimes_{\Lambda} H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, T^{*}(1)\right)^{\iota} \rightarrow \mathscr{H}(\Gamma) .
$$

For any $\eta \in \mathbf{D}_{\text {cris }}\left(V^{*}(1)\right)$ the element $\tilde{\eta}=\eta \otimes(1+X)$ lies in $\mathcal{D}\left(V^{*}(1)\right)$ and we define a map

$$
\mathfrak{L}_{V, 1-h, \eta}^{\varepsilon}: H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, V\right) \rightarrow \mathscr{H}(\Gamma)
$$

by

$$
\mathfrak{L}_{V, 1-h, \eta}^{\varepsilon}(x)=\left\langle x, \operatorname{Exp}_{V^{*}(1), h}^{\varepsilon^{-1}}(\tilde{\eta})^{\iota}\right\rangle_{V}
$$

Lemma 1.3.4. For any $j \in \mathbb{Z}$ one has

$$
\mathfrak{L}_{V(-1),-h, \eta \otimes e_{1}}^{\varepsilon}\left(\operatorname{Tw}_{V,-1}^{\varepsilon}(x)\right)=\operatorname{Tw}_{1}\left(\mathfrak{L}_{V, 1-h, \eta}^{\varepsilon}(x)\right) .
$$

Proof. A short computation shows that $\left\langle\mathrm{Tw}_{V, j}^{\varepsilon}(x), \mathrm{Tw}_{V^{*}(1),-j}^{\varepsilon}(y)\right\rangle_{V(j)}=\mathrm{Tw}_{-j}\langle x, y\rangle_{V}$. Taking into account that $\mathrm{Tw}_{V^{*}(1), 1}^{\varepsilon^{-1}}=-\mathrm{Tw}_{V^{*}(1), 1}^{\varepsilon}$ we have

$$
\begin{aligned}
& \mathfrak{L}_{V(-1),-h, \eta \otimes e_{1}}^{\varepsilon}\left(\operatorname{Tw}_{V,-1}^{\varepsilon}(x)\right)=\left\langle\operatorname{Tw}_{V,-1}^{\varepsilon}(x), \operatorname{Exp}_{V^{*}(2), h+1}^{\varepsilon^{-1}}\left(\widetilde{\eta \otimes e_{1}}\right)^{\iota}\right\rangle_{V(-1)}= \\
& \left\langle\operatorname{Tw}_{V,-1}^{\varepsilon}(x),-\operatorname{Tw}_{V^{*}(1), 1}^{\varepsilon^{-1}}\left(\operatorname{Exp}_{V^{*}(1), h}^{\varepsilon^{-1}}(\widetilde{\eta})\right)^{\iota}\right\rangle_{V(-1)}=\left\langle\operatorname{Tw}_{V,-1}^{\varepsilon}(x), \operatorname{Tw}_{V^{*}(1), 1}^{\varepsilon}\left(\operatorname{Exp}_{V^{*}(1), h}^{\varepsilon^{-1}}(\widetilde{\eta})\right)^{\iota}\right\rangle_{V(-1)}= \\
& \operatorname{Tw}_{1}\left\langle x, \operatorname{Exp}_{V^{*}(1), h}^{\varepsilon^{-1}}(\widetilde{\eta})^{\iota}\right\rangle_{V}=\operatorname{Tw}_{1}\left(\mathfrak{L}_{V, 1-h, \eta}^{\varepsilon}(x)\right)
\end{aligned}
$$

and the lemma is proved.
1.4. $p$-adic distributions (see [Cz6, Chapitre II], [PR2, Sections 1.1-1.2]). Let $\mathcal{D}\left(\mathbb{Z}_{p}^{*}, L\right)$ be the space of distributions on $\mathbb{Z}_{p}^{*}$ with values in a finite extensions $L$ of $\mathbb{Q}_{p}$. To each $\mu \in \mathcal{D}\left(\mathbb{Z}_{p}^{*}, L\right)$ one can associate its Amice transform $\mathscr{A}_{\mu}(X) \in L[[X]]$ by

$$
\mathscr{A}_{\mu}(X)=\int_{\mathbb{Z}_{p}^{*}}(1+X)^{x} \mu(x)=\sum_{n=0}^{\infty}\left(\int_{\mathbb{Z}_{p}^{*}}\binom{x}{n} \mu(x)\right) X^{n} .
$$

The map $\mu \mapsto \mathscr{A}_{\mu}(X)$ establishes an isomorphism between $\mathcal{D}\left(\mathbb{Z}_{p}^{*}, L\right)$ and $\left(\mathscr{R}_{L}^{+}\right)^{\psi=0}$. We will denote by $\mathbf{M}(\mu)$ the unique element of $\mathscr{H}(\Gamma)$ such that

$$
\mathbf{M}(\mu)(1+X)=\mathcal{A}_{\mu}(X)
$$

For each $m \in \mathbb{Z}$ the character $\chi^{m}: \Gamma \rightarrow \mathbb{Z}_{p}^{*}$ can be extended to a unique continuous $L$-linear map $\chi^{m}: \mathscr{H}(\Gamma) \rightarrow L^{*}$. If $h=\sum_{i=0}^{p-2} \delta_{i} h_{i}\left(\gamma_{1}-1\right)$, then $\chi^{m}(h)=h_{i}\left(\chi^{m}\left(\gamma_{1}\right)-1\right)$ with $i \equiv m(\bmod (p-1))$. An easy computation shows that

$$
\int_{\mathbb{Z}_{p}^{*}} x^{m} \mu(x)=\partial^{m} \mathscr{A}_{\mu}(0)=\chi^{m}(\mathbf{M}(\mu)) .
$$

If $x \in \mathbb{Z}_{p}^{*}$ we set $\langle x\rangle=\omega^{-1}(x) x$ where $\omega$ denotes the Teichmüller character. To any $\mu \in \mathcal{D}\left(\mathbb{Z}_{p}^{*}, L\right)$ we associate $p$-adic functions

$$
L_{p}\left(\mu, \omega^{i}, s\right)=\int_{\mathbb{Z}_{p}^{*}} \omega^{i}(x)\langle x\rangle^{s} \mu(x), \quad 0 \leqslant i \leqslant p-2 .
$$

Write $\mathbf{M}(\mu)=\sum_{i=0}^{p-2} \delta_{i} h_{i}\left(\gamma_{1}-1\right)$. Then

$$
\begin{equation*}
L_{p}\left(\mu, \omega^{i}, s\right)=h_{i}\left(\chi\left(\gamma_{1}\right)^{s}-1\right) \tag{8}
\end{equation*}
$$

To prove this formula it is enough to compare the values of the both sides at the integers $s \equiv i(\bmod (p-1))$.

We say that $\mu$ is of order $r>0$ if its Amice transform $\mathscr{A}_{\mu}(X)=\sum_{n=1}^{\infty} a_{n} X^{n}$ is of order $r$ i.e. if the sequence $\left|a_{n}\right|_{p} / n^{r}$ is bounded above. A distribution of order $r$ is completely determined by the values of the integrals

$$
\int_{\mathbb{Z}_{p}^{*}} \zeta_{p^{n}}^{x} x^{i} \mu(x), \quad n \in \mathbb{N}, \quad 0 \leqslant i \leqslant[r]
$$

where $[r]$ is the largest integer no greater then $r$.
Set $\hat{\mathbb{Z}}^{(p)}=\mathbb{Z}_{p}^{*} \times \prod_{l \neq p} \mathbb{Z}_{l}$. A locally analytic function on $\prod_{l \neq p} \mathbb{Z}_{l}$ is locally constant and we say that a distribution $\mu$ on $\hat{\mathbb{Z}}^{(p)}$ is of order $r$ if for any locally constant function $g(y)$ on $\prod_{l \neq p} \mathbb{Z}_{l}$ the linear map $f \mapsto \int_{\hat{\mathbb{Z}}^{(p)}} f(x) g(y) \mu(x, y)$ is a distribution of order $r$ on $\mathbb{Z}_{p}^{*}$.

## §2. The $\ell$-invariant

### 2.1. The $\ell$-invariant.

2.1.1. Definition of the $\ell$-invariant. In this section we review and generalise slightly the definition of the $\ell$-invariant proposed in our previous article [Ben2] in order to cover the case of potentially crystalline reduction of modular forms. Let $S$ be a finite set of primes and $\mathbb{Q}^{(S)} / \mathbb{Q}$ be the maximal Galois extension of $\mathbb{Q}$ unramified outside $S \cup\{\infty\}$. Fix a finite extension $L / \mathbb{Q}_{p}$. Let $V$ be an $L$-adic representation of $G_{S}$ i.e. a finite dimensional $L$-vector space equipped with a continuous linear action of $G_{S}$. We write $H_{S}^{*}(\mathbb{Q}, V)$ for the continuous cohomology of $G_{S}$ with coefficients in $V$. We will always assume that the restriction of $V$ on the decomposition group at $p$ is potentially semistable. For all primes $l \neq p$ (resp. for $l=p$ ) Greenberg [Gre1] (resp. Bloch and Kato [BK]) defined a subgroup $H_{f}^{1}\left(\mathbb{Q}_{l}, V\right)$ of $H^{1}\left(\mathbb{Q}_{l}, V\right)$ by

$$
H_{f}^{1}\left(\mathbb{Q}_{l}, V\right)= \begin{cases}\operatorname{ker}\left(H^{1}\left(\mathbb{Q}_{l}, V\right) \rightarrow H^{1}\left(\mathbb{Q}_{l}^{\text {ur }}, V\right)\right) & \text { if } l \neq p \\ \operatorname{ker}\left(H^{1}\left(\mathbb{Q}_{p}, V\right) \rightarrow H^{1}\left(\mathbb{Q}_{p}, V \otimes \mathbf{B}_{\text {cris }}\right)\right) & \text { if } l=p\end{cases}
$$

where $\mathbf{B}_{\text {cris }}$ is the ring of crystalline periods [Fo2]. The Selmer group of $V$ is defined as

$$
H_{f}^{1}(\mathbb{Q}, V)=\operatorname{ker}\left(H_{S}^{1}(\mathbb{Q}, V) \rightarrow \bigoplus_{l \in S} \frac{H^{1}\left(\mathbb{Q}_{l}, V\right)}{H_{f}^{1}\left(\mathbb{Q}_{l}, V\right)}\right)
$$

We also define

$$
H_{f,\{p\}}^{1}(\mathbb{Q}, V)=\operatorname{ker}\left(H_{S}^{1}(\mathbb{Q}, V) \rightarrow \bigoplus_{l \in S-\{p\}} \frac{H^{1}\left(\mathbb{Q}_{l}, V\right)}{H_{f}^{1}\left(\mathbb{Q}_{l}, V\right)}\right)
$$

Note that these definitions do not depend on the choice of $S$. From now until the end of this $\S$ we assume that $V$ satisfies the following conditions

1) $H_{f}^{1}(\mathbb{Q}, V)=H_{f}^{1}\left(\mathbb{Q}, V^{*}(1)\right)=0$.
2) The action of $\varphi$ on $\mathbf{D}_{\text {st }}(V)$ is semisimple at 1 .
3) $\operatorname{dim}_{L} t_{V}\left(\mathbb{Q}_{p}\right)=1$.

We remark that the last condition can be relaxed but it simplifies the formulation of Proposition 2.2.4 below and holds for the situations considered in $\S \S 3-4$.

The condition 1) together with the Poitou-Tate exact sequence (see [FP, Proposition 2.2.1])

$$
\cdots \rightarrow H_{f}^{1}(\mathbb{Q}, V) \rightarrow H_{S}^{1}(\mathbb{Q}, V) \simeq \bigoplus_{l \in S} \frac{H^{1}\left(\mathbb{Q}_{l}, V\right)}{H_{f}^{1}\left(\mathbb{Q}_{l}, V\right)} \rightarrow H_{f}^{1}\left(\mathbb{Q}, V_{f}^{*}(1)\right)^{*} \rightarrow \cdots
$$

gives an isomorphism

$$
H_{S}^{1}(\mathbb{Q}, V) \simeq \bigoplus_{l \in S} \frac{H^{1}\left(\mathbb{Q}_{l}, V\right)}{H_{f}^{1}\left(\mathbb{Q}_{l}, V\right)}
$$

In particular, we have

$$
\begin{equation*}
H_{f,\{p\}}^{1}(\mathbb{Q}, V) \simeq \frac{H^{1}\left(\mathbb{Q}_{p}, V\right)}{H_{f}^{1}\left(\mathbb{Q}_{p}, V\right)} \tag{9}
\end{equation*}
$$

Let $D$ be a one-dimensional subspace of $\mathbf{D}_{\text {cris }}(V)$ on which $\varphi$ acts as multiplication by $p^{-1}$. Set $D_{\mathbb{Q}_{p}^{\text {ur }}}=$ $D \otimes_{\mathbb{Q}_{p}} \mathbb{Q}_{p}^{\text {ur }}$ where $\mathbb{Q}_{p}^{\text {ur }}$ denotes the maximal unramified extension of $\mathbb{Q}_{p}$. Using the weak admissibility of $\mathbf{D}_{\text {pst }}(V)$ it is easy to see that $D$ is not contained in $\operatorname{Fil}^{0} \mathbf{D}_{\text {cris }}(V)$ and therefore

$$
\begin{equation*}
\mathbf{D}_{\mathrm{pst}}(V)=\operatorname{Fil}^{0} \mathbf{D}_{\mathrm{pst}}(V) \oplus D_{\mathbb{Q}_{p}^{\mathrm{ur}}} \tag{10}
\end{equation*}
$$

as $\mathbb{Q}_{p}^{\text {ur }} \otimes_{\mathbb{Q}_{p}} L$-modules. Let $m$ denote the unique Hodge-Tate weight of $D$. By Berger's theory [Ber4] (see also [BC, Section 2.4.2]), the intersection $\mathbf{D}_{\mathrm{rig}}^{\dagger}(V) \cap\left(D \otimes_{L} \mathscr{R}_{L}[1 / t]\right)$ is a saturated ( $\left.\varphi, \Gamma\right)$-submodule of $\mathbf{D}_{\text {rig }}^{\dagger}(V)$ of rank 1 which is isomorphic to $\mathscr{R}_{L}(\delta)$ with $\delta(x)=|x| x^{m}$. Thus we have an exact sequence of $(\varphi, \Gamma)$-modules

$$
\begin{equation*}
0 \rightarrow \mathscr{R}_{L}(\delta) \rightarrow \mathbf{D}_{\mathrm{rig}}^{\dagger}(V) \rightarrow \mathbf{D} \rightarrow 0 \tag{11}
\end{equation*}
$$

where $\mathbf{D}=\mathbf{D}_{\mathrm{rig}}^{\dagger}(V) / \mathscr{R}_{L}(\delta)$. Passing to duals and taking the long exact cohomology sequence we obtain an exact sequence

$$
\begin{equation*}
H^{1}\left(\mathbb{Q}_{p}, V^{*}(1)\right) \rightarrow H^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right) \rightarrow H^{2}\left(\mathbf{D}^{*}(\chi)\right) . \tag{12}
\end{equation*}
$$

Proposition 2.1.2. Assume that one of the following conditions holds
a) $D$ is not contained in the image of the monodromy operator $N: \mathbf{D}_{\mathrm{pst}}(V) \rightarrow \mathbf{D}_{\mathrm{pst}}(V)$ and $\mathbf{D}_{\text {cris }}(V)^{\varphi=1}=0$.
b) $D$ is contained in the image of $N$ and $N^{-1}(D) \cap \mathbf{D}_{\text {st }}(V)^{\varphi=1}$ is a one-dimensional L-vector space. Then the composition

$$
\varkappa: H_{f,\{p\}}^{1}\left(\mathbb{Q}, V^{*}(1)\right) \rightarrow H^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)
$$

of the localisation map $H_{f,\{p\}}^{1}\left(\mathbb{Q}, V^{*}(1)\right) \rightarrow H^{1}\left(\mathbb{Q}_{p}, V^{*}(1)\right)$ with $H^{1}\left(\mathbb{Q}_{p}, V^{*}(1)\right) \rightarrow H^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)$ is injective. Moreover, $\operatorname{Im}(\varkappa)$ is a one-dimensional L-vector space such that

$$
\operatorname{Im}(\varkappa) \cap H_{f}^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)=\{0\} .
$$

Proof. We consider the two cases separately.
a) First assume that $D$ satisfies a). Applying the functor $\mathscr{D}_{\text {pst }}$ to (11) we obtain an exact sequence

$$
\begin{equation*}
0 \rightarrow D_{\mathbb{Q}_{p}^{\text {ur }}} \rightarrow \mathbf{D}_{\mathrm{pst}}(V) \xrightarrow{f} \mathscr{D}_{\mathrm{pst}}(\mathbf{D}) \rightarrow 0 . \tag{13}
\end{equation*}
$$

From (10) it follows that $\mathrm{Fil}^{0} \mathscr{D}_{\text {pst }}(\mathbf{D})=\mathscr{D}_{\mathrm{pst}}(\mathbf{D})$ and by [Ben2, Proposition 1.4.4]

$$
H^{0}(\mathbf{D}) \simeq \mathscr{D}_{\mathrm{pst}}(\mathbf{D})^{\varphi=1, N=0, G_{\mathbb{Q}_{p}}}=\mathscr{D}_{\mathrm{cris}}(\mathbf{D})^{\varphi=1}
$$

Applying the snake lemma to (13) we obtain an isomorphism of $G_{\mathbb{Q}_{p}}$-modules $\mathbf{D}_{\mathrm{pst}}(V)^{\varphi=1} \simeq \mathscr{D}_{\mathrm{pst}}(\mathbf{D})^{\varphi=1}$. Thus $\mathbf{D}_{\text {st }}(V)^{\varphi=1} \simeq \mathscr{D}_{\text {st }}(\mathbf{D})^{\varphi=1}$. Let $x \in \mathscr{D}_{\text {cris }}(\mathbf{D})^{\varphi=1}$. There exists a unique $y \in \mathbf{D}_{\text {st }}(V)^{\varphi=1}$ such that $f(y)=x$. Since $f(N(y))=N(x)=0$, one has $N(y) \in D$ and by a) $N(y)=0$ i.e. $y \in \mathbf{D}_{\text {cris }}(V)^{\varphi=1}$. Since $\mathbf{D}_{\text {cris }}(V)^{\varphi=1}=0$ by assumption a), we proved that $H^{0}(\mathbf{D})=0$.

Now $H^{2}\left(\mathbf{D}^{*}(\chi)\right)=0$ by Poincaré duality and from the exact sequence (12) we obtain that the map $H^{1}\left(\mathbb{Q}_{p}, V^{*}(1)\right) \rightarrow H^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)$ is surjective. Since $\chi \delta^{-1}(x)=x^{1-m}$, the cohomology $H^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)$ decomposes into the direct sum of one dimensional subspaces

$$
H^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right) \simeq H_{f}^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right) \oplus H_{c}^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)
$$

The image of $H_{f}^{1}\left(\mathbb{Q}_{p}, V^{*}(1)\right)$ in $H^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)$ is contained in $H_{f}^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)$ and we have a surjective map

$$
\begin{equation*}
\frac{H^{1}\left(\mathbb{Q}_{p}, V^{*}(1)\right)}{H_{f}^{1}\left(\mathbb{Q}_{p}, V^{*}(1)\right)} \rightarrow \frac{H^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)}{H_{f}^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)} \tag{14}
\end{equation*}
$$

From $\mathbf{D}_{\text {cris }}(V)^{\varphi=1}=0$ it follows that $H^{0}\left(\mathbb{Q}_{p}, V\right)=0$ and

$$
\operatorname{dim}_{L}\left(H_{f}^{1}\left(\mathbb{Q}_{p}, V\right)\right)=\operatorname{dim}_{L}\left(t_{V}(L)\right)+\operatorname{dim}_{L}\left(H^{0}\left(\mathbb{Q}_{p}, V\right)\right)=1
$$

Therefore $H^{1}\left(\mathbb{Q}_{p}, V^{*}(1)\right) / H_{f}^{1}\left(\mathbb{Q}_{p}, V^{*}(1)\right)$ is one-dimensional and the map (14) is an isomorphism. The Proposition follows now from this fact and from the isomorphism (9) for the cohomology with coefficients in $V^{*}(1)$ instead $V$.
b) Now assume that $D$ satisfies b). We follow the approach of [Ben2, Sections 2.1 and 2.2] with some modifications ( see especially the proofs of Proposition 2.1.7 and Lemma 2.1.8 of op. cit.). The Proposition will be proved in several steps.
b1) Consider the filtration on $\mathbf{D}_{\text {pst }}(V)$ given by

$$
D_{i}= \begin{cases}0 & \text { if } i=-1 \\ D_{\mathbb{Q}_{p}^{\text {ur }}} & \text { if } i=0 \\ \left(D+N^{-1}(D) \cap \mathbf{D}_{\mathrm{st}}(V)^{\varphi=1}\right)_{\mathbb{Q}_{p}^{\text {ur }}} & \text { if } i=1 \\ \mathbf{D}_{\mathrm{pst}}(V) & \text { if } i=2 .\end{cases}
$$

By [Ber4] this filtration induces a unique filtration on $\mathbf{D}_{\text {rig }}^{\dagger}(V)$

$$
\{0\}=F_{-1} \mathbf{D}_{\text {rig }}^{\dagger}(V) \subset F_{0} \mathbf{D}_{\text {rig }}^{\dagger}(V) \subset F_{1} \mathbf{D}_{\text {rig }}^{\dagger}(V) \subset F_{2} \mathbf{D}_{\text {rig }}^{\dagger}(V)=\mathbf{D}_{\text {rig }}^{\dagger}(V)
$$

such that $\mathscr{D}_{\mathrm{pst}}\left(F_{i} \mathbf{D}_{\mathrm{rig}}^{\dagger}(V)\right)=D_{i}$. Note that $F_{1} \mathbf{D}_{\mathrm{rig}}^{\dagger}(V)$ is a semistable $(\varphi, \Gamma)$-submodule of $\mathbf{D}_{\mathrm{rig}}^{\dagger}(V)$. To simplify notation set $M_{0}=F_{0} \mathbf{D}_{\text {rig }}^{\dagger}(V), M=F_{1} \mathbf{D}_{\text {rig }}^{\dagger}(V)$ and $M_{1}=\operatorname{gr}_{1} \mathbf{D}_{\mathrm{rig}}^{\dagger}(V)$. We remark that $M_{0} \simeq \mathscr{R}_{L}(\delta)$ and since $\operatorname{Fil}^{0}\left(D_{1} / D_{0}\right)=D_{1} / D_{0}$ and $\left(D_{0} / D_{1}\right)^{\varphi=1}=D_{0} / D_{1}$ Proposition 1.5.9 of [Ben2]
implies that $M_{1} \simeq \mathscr{R}_{L}\left(x^{-k}\right)$ for some $k \geqslant 0$. By the assumption b) the monodromy operator $N$ acts non trivially on $D_{1}$ and therefore we have a non crystalline extension

$$
0 \rightarrow \mathscr{R}_{L}(\delta) \rightarrow M \rightarrow \mathscr{R}_{L}\left(x^{-k}\right) \rightarrow 0
$$

which is a particular case of the exact sequence from [Ben2, Proposition 2.1.7]. Passing to duals and taking the long cohomology sequence we obtain a diagram

$$
\begin{align*}
H^{1}\left(\mathscr{R}_{L}\left(|x| x^{k+1}\right)\right) \xrightarrow{f_{1}} H^{1}\left(M^{*}(\chi)\right) \xrightarrow{g_{1}} H^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right) \xrightarrow{\delta_{1}} H^{2}\left(\mathscr{R}_{L}\left(|x| x^{k+1}\right)\right) \longrightarrow 0 .  \tag{15}\\
H_{f,\{p\}}^{1}\left(\mathbb{Q}, V^{*}(1)\right)
\end{align*}
$$

b2) The quotient $\mathbf{D}=\operatorname{gr}_{2} \mathbf{D}_{\mathrm{rig}}^{\dagger}(V)$ is a potentially semistable $(\varphi, \Gamma)$-module with Hodge-Tate weights $\geqslant 0$. Thus $H^{0}(\mathbf{D}) \simeq\left(\mathbf{D}_{\mathrm{pst}}(V) / D_{1}\right)^{G_{\mathbb{Q}_{p}}, \varphi=1, N=0}$. Let $\bar{x}=x+D_{1} \in\left(\mathbf{D}_{\mathrm{pst}}(V) / D_{1}\right)^{G_{Q_{p}}, \varphi=1, N=0}$. For each $g \in G_{\mathbb{Q}_{p}}$ we can write $g(x)=x+d$ for some $d \in D_{1}$. Since the inertia subgroup $I_{p} \subset G_{\mathbb{Q}_{p}}$ acts on $\mathbf{D}_{\mathrm{pst}}(V)$ through a finite quotient and since the restriction of this action on $D_{1}$ is trivial, we obtain that $x \in \mathbf{D}_{\mathrm{pst}}(V)^{I_{p}}=\mathbf{D}_{\mathrm{st}}(V) \otimes_{\mathbb{Q}_{p}} \mathbb{Q}_{p}^{u r}$. Thus

$$
\bar{x} \in\left(\left(\frac{\mathbf{D}_{\mathrm{st}}(V)}{D+N^{-1}(D) \cap \mathbf{D}_{\mathrm{st}}(V)^{\varphi=1}}\right) \otimes \mathbb{Q}_{p}^{u r}\right)^{G_{\mathbb{Q}_{p}, \varphi=1, N=0}}=\left(\frac{\mathbf{D}_{\mathrm{st}}(V)}{D+N^{-1}(D) \cap \mathbf{D}_{\mathrm{st}}(V)^{\varphi=1}}\right)^{\varphi=1, N=0} .
$$

Since $\varphi$ is semisimple at 1 , we can assume that $x \in \mathbf{D}_{\text {st }}(V)^{\varphi=1}$. Then $N(x) \in D$ and therefore $x \in$ $N^{-1}(D) \cap \mathbf{D}_{\text {st }}(V)^{\varphi=1}$. This shows that $\bar{x}=0$ and we proved that $H^{0}(\mathbf{D})=0$. By Poincaré duality we obtain immediately that $H^{2}\left(\mathbf{D}^{*}(\chi)\right)=0$. Now the Euler characteristic formula together with [Ben2, Corollary 1.4.5] give

$$
\left.\operatorname{dim}_{L} H^{1}\left(\mathbf{D}^{*}(\chi)\right)\right)=\operatorname{rg}\left(\mathbf{D}^{*}(\chi)\right)+\operatorname{dim}_{L} H^{0}\left(\mathbf{D}^{*}(\chi)\right)=\operatorname{dim}_{L} H_{f}^{1}\left(\mathbf{D}^{*}(\chi)\right)
$$

and therefore

$$
\begin{equation*}
H_{f}^{1}\left(\mathbf{D}^{*}(\chi)\right)=H^{1}\left(\mathbf{D}^{*}(\chi)\right) . \tag{16}
\end{equation*}
$$

b3) Consider the exact sequence

$$
0 \rightarrow \mathbf{D}^{*}(\chi) \rightarrow \mathbf{D}_{\text {rig }}^{\dagger}\left(V^{*}(1)\right) \rightarrow M^{*}(\chi) \rightarrow 0
$$

Since $H^{0}\left(M^{*}(\chi)\right)=0$, this sequence together with the isomorphism (16) give an exact sequence

$$
\begin{equation*}
0 \rightarrow H_{f}^{1}\left(\mathbf{D}^{*}(\chi)\right) \rightarrow H^{1}\left(\mathbb{Q}_{p}, V^{*}(1)\right) \rightarrow H^{1}\left(M^{*}(\chi)\right) \rightarrow 0 \tag{17}
\end{equation*}
$$

On the other hand, by [Ben2, Corollary 1.4.6] the sequence

$$
\begin{equation*}
0 \rightarrow H_{f}^{1}\left(\mathbf{D}^{*}(\chi)\right) \rightarrow H_{f}^{1}\left(\mathbb{Q}_{p}, V^{*}(1)\right) \rightarrow H_{f}^{1}\left(M^{*}(\chi)\right) \rightarrow 0 \tag{18}
\end{equation*}
$$

is also exact.
b4) We come back to the diagram (15). The sequences (17) and (18) together with the isomorphism (9) show that the map $\eta$ is injective. By [Ben2, Lemma 2.1.8] one has $\operatorname{ker}\left(g_{1}\right)=H_{f}^{1}\left(M^{*}(\chi)\right)$ and $H^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)=H_{f}^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right) \oplus \operatorname{Im}\left(g_{1}\right)$. Since

$$
H^{1}\left(\mathbb{Q}_{p}, V^{*}(1)\right) / H_{f}^{1}\left(\mathbb{Q}_{p}, V^{*}(1)\right) \simeq H^{1}\left(M^{*}(\chi)\right) / H_{f}^{1}\left(M^{*}(\chi)\right)
$$

we obtain that $\operatorname{ker}(\varkappa)=\operatorname{Im}(\eta) \cap \operatorname{ker}\left(g_{1}\right)=0$ and that $\operatorname{Im}(\varkappa) \cap H_{f}^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)=0$. The Proposition is proved.

Definition. The $\ell$-invariant associated to $V$ and $D$ is the unique element $\ell(V, D) \in L$ such that

$$
\operatorname{Im}(\varkappa)=L\left(\mathbf{y}_{m-1}+\ell(V, D) \mathbf{x}_{m-1}\right) .
$$

Here $\left\{\mathbf{x}_{m-1}, \mathbf{y}_{m-1}\right\}$ is the canonical basis of $H^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)$ constructed in 1.2.5.
Remarks 2.1.3. 1) If $V$ is semistable at $p$ this definition agrees with the definition of $\ell(V, D)$ proposed in [Ben2, Sections 2.2.2 and 2.3.3].
2) The assumptions a) and b) imply both that $H^{0}\left(\mathbb{Q}_{p}, V\right)=0$.
3) One can express $\ell(V, D)$ directly in terms of $V$ and $D$. Assume that $D$ satisfies the condition a) of Proposition 2.1.2. Since $H^{0}(\mathbf{D})=0$ the sequence (11) shows that $H^{1}\left(\mathscr{R}_{L}(\delta)\right)$ injects into $H^{1}\left(\mathbf{D}_{\mathrm{rig}}^{\dagger}(V)\right) \simeq$ $H^{1}\left(\mathbb{Q}_{p}, V\right)$. Moreover, from $\operatorname{dim}_{L} H_{f}^{1}\left(\mathbb{Q}_{p}, V\right)=1$ and the fact that $\operatorname{dim}_{L} H_{f}^{1}\left(\mathscr{R}_{L}(\delta)\right)=1$ it follows that $H_{f}^{1}\left(\mathbb{Q}_{p}, V\right) \simeq H_{f}^{1}\left(\mathscr{R}_{L}(\delta)\right)$. Let $H_{D}^{1}(V)$ denote the inverse image of $H^{1}\left(\mathscr{R}_{L}(\delta)\right) / H_{f}^{1}\left(\mathscr{R}_{L}(\delta)\right)$ under the isomorphism (9). Then

$$
H_{D}^{1}(V) \simeq \frac{H^{1}\left(\mathscr{R}_{L}(\delta)\right)}{H_{f}^{1}\left(\mathscr{R}_{L}(\delta)\right)}
$$

and the localisation map $H_{S}^{1}(V) \rightarrow H^{1}\left(\mathbb{Q}_{p}, V\right)$ induces an injection $H_{D}^{1}(V) \rightarrow H^{1}\left(\mathscr{R}_{L}(\delta)\right)$. Using the decomposition (6) we define $\mathscr{L}(V, D)$ as the unique element of $L$ such that

$$
\operatorname{Im}\left(H_{D}^{1}(V) \rightarrow H^{1}\left(\mathscr{R}_{L}(\delta)\right)\right)=L\left(\boldsymbol{\beta}_{m}+\mathscr{L}(V, D) \boldsymbol{\alpha}_{m}\right)
$$

where $\left\{\boldsymbol{\alpha}_{m}, \boldsymbol{\beta}_{m}\right\}$ denotes the canonical basis of $H^{1}\left(\mathscr{R}_{L}(\delta)\right)$. Then

$$
\begin{equation*}
\ell(V, D)=-\mathscr{L}(V, D) \tag{19}
\end{equation*}
$$

(see [Ben2, Proposition 2.2.7]). Note that in op. cit. $V$ is assumed to be semistable, but in the potentially semistable case the proof is exactly the same.

A similar duality formula can be proved in the case b) too, but it will not be used in this paper. We refer to [Ben2, Section 2.2.3] for more detail.
4) The diagram (15) shows that in the case b) the image of $H_{f,\{p\}}^{1}\left(\mathbb{Q}, V^{*}(1)\right)$ in $H^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)$ coincides with $\operatorname{Im}\left(g_{1}\right)$ and therefore that $\ell(V, D)$ depends only on the local properties of $V$ at $p$. On the other hand, in the case a) the $\ell$ invariant is global and contains information about the localisation map $H_{f,\{p\}}^{1}\left(\mathbb{Q}, V^{*}(1)\right) \rightarrow H^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)$.

### 2.2. Relation to the large exponential map.

2.2.1. Derivative of the large exponential map. In this section we interpret $\ell(V, D)$ in terms of the Bockstein homomorphism associated to the large exponential map. This interpretation is crucial for the proof of the main theorem of this paper. We keep the notations and conventions of Section 2.1. Recall (see Section 1.3.2) that $H^{1}\left(\mathbb{Q}_{p}, \mathscr{H}(\Gamma) \otimes_{\mathbb{Q}_{p}} V\right)=\mathscr{H}(\Gamma) \otimes_{\Lambda_{\mathbb{Q}_{p}}} H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, V\right)$ injects into $\mathbf{D}_{\text {rig }}^{\dagger}(V)$. Set

$$
H_{\delta}^{1}\left(\mathbb{Q}_{p}, \mathscr{H}(\Gamma) \otimes_{\mathbb{Q}_{p}} V\right)=\mathscr{R}_{L}(\delta) \cap H^{1}\left(\mathbb{Q}_{p}, \mathscr{H}(\Gamma) \otimes_{\mathbb{Q}_{p}} V\right) .
$$

The projection map induces a commutative diagram

where the bottom arrow is an injection. We fix a generator $\gamma \in \Gamma$ and an integer $h \geqslant 1$ such that $\operatorname{Fil}^{-h} \mathbf{D}_{\mathrm{dR}}(V)=\mathbf{D}_{\mathrm{dR}}(V)$.

Proposition 2.2.2. Assume that $D$ is a one-dimensional subspace of $\mathbf{D}_{\text {cris }}(V)$ on which $\varphi$ acts as multiplication by $p^{-1}$. For any $a \in D$ let $x \in \mathcal{D}(V)$ be such that $x(0)=a$. Then
i) There exists a unique $F \in H_{\delta}^{1}\left(\mathbb{Q}_{p}, \mathscr{H}(\Gamma) \otimes V\right)$ such that

$$
(\gamma-1) F=\operatorname{Exp}_{V, h}^{\varepsilon}(x) .
$$

ii) The composition map

$$
\begin{aligned}
& \delta_{D}: D \rightarrow H_{\delta}^{1}\left(\mathbb{Q}_{p}, \mathscr{H}(\Gamma) \otimes V\right) \rightarrow H^{1}\left(\mathscr{R}_{L}(\delta)\right) \\
& \delta_{D}(a)=\operatorname{pr}_{0}(F)
\end{aligned}
$$

is well defined and is explicitly given by the following formula

$$
\delta_{D}(a)=\Gamma(h)\left(1-\frac{1}{p}\right)^{-1}(\log \chi(\gamma))^{-1} i_{c}(a) .
$$

Proof. 1) Since in both cases, a) and b) $\mathbf{D}_{\text {cris }}(V)^{\varphi=1}=0$, the operator $1-\varphi$ is invertible on $\mathbf{D}_{\text {cris }}(V)$ and we have a diagram

where $\Xi_{V, 0}^{\varepsilon}(f)=\left(\frac{1-p^{-1} \varphi^{-1}}{1-\varphi} f(0), 0\right)$. If $x \in D \otimes \mathscr{R}_{L}^{\psi=0}$ then $\Xi_{V, 0}^{\varepsilon}(x)=0$ and $\operatorname{pr}_{0}\left(\operatorname{Exp}_{V, h}^{\varepsilon}(x)\right)=0$. On the other hand, as $H_{\mathrm{IW}}^{1}\left(\mathbb{Q}_{p}, V\right)$ is $\Lambda_{\mathbb{Q}_{p}}$ free, the map $\left(\mathscr{H}(\Gamma) \otimes_{\Lambda_{\mathbb{Q}_{p}}} H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, V\right)\right)_{\Gamma} \rightarrow H^{1}\left(\mathbb{Q}_{p}, V\right)$ is injective and therefore there exists a unique $F \in \mathscr{H}(\Gamma) \otimes_{\Lambda_{\mathbb{Q}_{p}}} H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, V\right)$ such that $\operatorname{Exp}_{V, h}^{\varepsilon}(x)=(\gamma-1) F$. Let $y \in D \otimes \mathscr{R}_{L}^{\psi=0}$ be another element such that $y(0)=a$ and let $\operatorname{Exp}_{V, h}^{\varepsilon}(y)=(\gamma-1) G$. Since $\mathscr{R}_{L}^{\psi=0}=\mathscr{H}(\Gamma)(1+X)$ we have $y=x+(\gamma-1) g$ for some $g \in D \otimes \mathscr{R}_{L}^{\psi=0}$. As $\operatorname{Exp}_{V, h}^{\varepsilon}(g)=0$, we obtain immediately that $\operatorname{pr}_{0}(G)=\operatorname{pr}_{0}(F)$ and we proved that the map $\delta_{D}$ is well defined.
2) Take $a \in D$ and set

$$
x=a \otimes \ell\left(\frac{(1+X)^{\chi(\gamma)}-1}{X}\right),
$$

where $\ell(u)=\frac{1}{p} \log \left(\frac{u^{p}}{\varphi(u)}\right)$. An easy computation shows that

$$
\sum_{\zeta^{p}=1} \ell\left(\frac{\zeta^{\chi(\gamma)}(1+X)^{\chi(\gamma)}-1}{\zeta(1+X)-1}\right)=0 .
$$

Thus $x \in D \otimes O_{L}[[X]]^{\psi=0}$. Write $x$ in the form $f=(1-\varphi)(\gamma-1)(a \otimes \log (X))$. Then

$$
\Omega_{V, h}^{\varepsilon}(x)=(-1)^{h-1} \frac{\log \chi\left(\gamma_{1}\right)}{p} t^{h} \partial^{h}\left((\gamma-1)(a \log (X))=\left(1-\frac{1}{p}\right) \log \chi(\gamma)(\gamma-1) F\right.
$$

where

$$
F=(-1)^{h-1} t^{h} \partial^{h}(a \log (X))=(-1)^{h-1} a t^{h} \partial^{h-1}\left(\frac{1+X}{X}\right) .
$$

This implies immediately that $F \in H_{\delta}^{1}\left(\mathbb{Q}_{p}, \mathscr{H}(\Gamma) \otimes V\right)$. On the other hand, as $D=\mathcal{D}_{\text {cris }}\left(\mathscr{R}_{L}(\delta)\right)$ without lost of generality we may assume that $a=t^{-m} e_{\delta}$ where $\delta(x)=|x| x^{m}$. Then

$$
F=(-1)^{h-1} t^{h-m} \partial^{h} \log (X) e_{\delta}
$$

One has $\operatorname{pr}_{0}(F)=\operatorname{cl}(G, F)$ where $(1-\gamma) G=(1-\varphi) F$ (see Section 1.2.3) and by [CC1, Lemma 1.5.1] there exists a unique $b \in \mathscr{E}_{L}^{\dagger, \psi=0}$ such that $(1-\gamma) b=\ell(X)$. One has

$$
(1-\gamma)\left(t^{h-m} \partial^{h} b e_{\delta}\right)=(1-\varphi)\left(t^{h-m} \partial^{h} \log (X) e_{\delta}\right)=(-1)^{h-1}(1-\varphi) F
$$

Thus $G=(-1)^{h-1} t^{h-m} \partial^{h}(b) e_{\delta}$ and res $\left(G t^{m-1} d t\right)=(-1)^{h-1}$ res $\left(t^{h-1} \partial^{h}(b) d t\right) e_{\delta}=0$. Next from the congruence $F \equiv(h-1)!t^{-m} e_{\delta}\left(\bmod \mathbb{Q}_{p}[[X]] e_{\delta}\right)$ it follows that $\operatorname{res}\left(F t^{m-1} d t\right)=(h-1)!e_{\delta}$. Therefore by [Ben2, Corollary 1.5.5] we have

$$
\begin{equation*}
\left(1-\frac{1}{p}\right)(\log \chi(\gamma)) \operatorname{cl}(G, F)=(h-1)!\operatorname{cl}\left(\boldsymbol{\beta}_{m}\right)=(h-1)!i_{c}(a) . \tag{20}
\end{equation*}
$$

On the other hand

$$
\begin{equation*}
x(0)=\left.a \otimes \ell\left(\frac{(1+X)^{\chi(\gamma)}-1}{X}\right)\right|_{X=0}=a\left(1-\frac{1}{p}\right) \log \chi(\gamma) . \tag{21}
\end{equation*}
$$

The formulas (20) and (21) imply that

$$
\delta_{D}(a)=(h-1)!\left(1-\frac{1}{p}\right)^{-1}(\log \chi(\gamma))^{-1} i_{c}(a) .
$$

and the Proposition is proved.
2.2.3. Derivative of the large logarithmic map and $\ell$-invariant. Fix a non-zero element $d \in D$ and consider the large logarithmic map

$$
\mathfrak{L}_{V^{*}(1), 1-h, d}^{\varepsilon}: H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, V^{*}(1)\right) \rightarrow \mathscr{H}(\Gamma)
$$

(see Section 1.3.3). Let
denote the global Iwasawa cohomology with coefficients in $T^{*}(1)$ and let

$$
H_{\mathrm{Iw}, S}^{1}\left(\mathbb{Q}, V^{*}(1)\right)=H_{\mathrm{Iw}, S}^{1}\left(\mathbb{Q}, T^{*}(1)\right) \otimes_{\mathbb{Z}_{p}} \mathbb{Q}_{p}
$$

The main results of this paper will be directly deduced from the following statement.

Proposition 2.2.4. Assume that $D$ is a one-dimensional subspace of $\mathbf{D}_{\text {cris }}(V)$ on which $\varphi$ acts as multiplication by $p^{-1}$ and which satisfies one of the conditions $a-b$ ) of Proposition 2.1.2. Let $\mathbf{z} \in$ $H_{\mathrm{Iw}, S}^{1}\left(\mathbb{Q}, V^{*}(1)\right)$. Assume that $\mathbf{z}_{0}=\operatorname{pr}_{0}(\mathbf{z}) \in H_{S}^{1}\left(\mathbb{Q}, V^{*}(1)\right)$ is non-zero and denote by $\mu_{\mathbf{z}} \in \mathcal{D}\left(\mathbb{Z}_{p}^{*}, L\right)$ the distribution defined by

$$
\mathbf{M}\left(\mu_{\mathbf{z}}\right)=\mathfrak{L}_{V^{*}(1), 1-h, d}^{\varepsilon}(\mathbf{z}) .
$$

Consider the p-adic function

$$
L_{p}\left(\mu_{\mathbf{z}}, s\right)=\int_{\mathbb{Z}_{p}^{*}}\langle x\rangle^{s} \mu_{\mathbf{z}}(x) .
$$

Then $L_{p}\left(\mu_{\mathbf{z}}, 0\right)=0$ and

$$
L_{p}^{\prime}\left(\mu_{\mathbf{z}}, 0\right)=\ell(V, D) \Gamma(h)\left(1-\frac{1}{p}\right)^{-1}\left[d, \exp _{V^{*}(1)}^{*}\left(\mathbf{z}_{0}\right)\right]_{V}
$$

where $[,]_{V}: \mathbf{D}_{\text {cris }}(V) \times \mathbf{D}_{\text {cris }}\left(V^{*}(1)\right) \rightarrow L$ is the canonical duality.
Proof. First note that by [PR1, Section 2.1.7] for $l \neq p$ one has $H_{\mathrm{IW}}^{1}\left(\mathbb{Q}_{l}, V^{*}(1)\right) \simeq H^{0}\left(\mathbb{Q}_{l}\left(\zeta_{p^{\infty}}\right), V^{*}(1)\right)$ and therefore $H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{l}, V^{*}(1)\right)_{\Gamma}$ is contained in $H_{f}^{1}\left(\mathbb{Q}_{l}, V^{*}(1)\right)$. Thus $H_{\mathrm{Iw}, S}^{1}\left(\mathbb{Q}, V^{*}(1)\right)_{\Gamma}$ injects into $H_{f,\{p\}}^{1}\left(\mathbb{Q}, V^{*}(1)\right)$ and $\mathbf{z}_{0} \in H_{f,\{p\}}^{1}\left(\mathbb{Q}, V^{*}(1)\right)$. Recall that we fixed a basis $d$ of the one-dimensional $L$-vector space $D=\mathscr{D}_{\text {cris }}\left(\mathscr{R}_{L}(\delta)\right)$. Let $d^{*}$ be the basis of $\mathscr{D}_{\text {cris }}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)$ which is dual to $d$. Let $\tilde{\mathbf{z}}_{0}$ denote the image of $\mathbf{z}_{0}$ under the projection map $H^{1}\left(\mathbf{D}_{\text {rig }}^{\dagger}\left(V^{*}(1)\right)\right) \rightarrow H^{1}\left(\mathscr{R}_{L}\left(\chi \delta^{-1}\right)\right)$. Write $\tilde{\mathbf{z}}_{0}=$ $a i_{f}\left(d^{*}\right)+b i_{c}\left(d^{*}\right)$. Then $\ell(V, D)=a / b$. By Proposition 1.2.6 and (7) we have

$$
\begin{align*}
& {\left[d, \exp _{V^{*}(1)}^{*}\left(\mathbf{z}_{0}\right)\right]_{V}=-\exp _{V}(d) \cup \mathbf{z}_{0}=-\exp _{\mathscr{R}_{L}(\delta)}(d) \cup \tilde{\mathbf{z}}_{0}=}  \tag{22}\\
& \quad=-b\left(i_{f}(d) \cup i_{c}\left(d^{*}\right)\right)=-b\left(\boldsymbol{\alpha}_{m} \cup \mathbf{y}_{m-1}\right)=b .
\end{align*}
$$

Let $\mathbf{M}\left(\mu_{\mathbf{z}}\right)=\sum_{i=0}^{p-2} \delta_{i} h_{i}\left(\gamma_{1}-1\right)$. Then $L_{p}\left(\mu_{\mathbf{z}}, s\right)=h_{0}\left(\chi\left(\gamma_{1}\right)^{s}-1\right)$ by (8). From Proposition 2.2.2 it follows that there exists $F \in H_{\delta}^{1}\left(\mathbb{Q}_{p}, \mathscr{H}(\Gamma) \otimes V\right)$ such that $\operatorname{Exp}_{V, h}^{\varepsilon^{-1}}(d \otimes(1+X))=(\gamma-1) F$ and

$$
\mathbf{M}\left(\mu_{\mathbf{z}}\right)=\mathfrak{L}_{V^{*}(1), 1-h, d}^{\varepsilon}(\mathbf{z})=\left\langle\mathbf{z}, \operatorname{Exp}_{V, h}^{\varepsilon^{-1}}\left(d \otimes(1+X)^{\iota}\right\rangle_{V}=\left(\gamma^{-1}-1\right)\left\langle\mathbf{z}, F^{\iota}\right\rangle_{V}\right.
$$

$\operatorname{Put}\left\langle\mathbf{z}, F^{\iota}\right\rangle_{V_{f}}=\sum_{i=0}^{p-2} \delta_{i} H_{i}\left(\gamma_{1}-1\right)$. Then $L_{p}\left(\mu_{\mathbf{z}}, s\right)=\left(\chi(\gamma)^{-s}-1\right) H_{0}\left(\chi\left(\gamma_{1}\right)^{s}-1\right)$. Since $\chi\left(\gamma_{1}\right)=\chi(\gamma)^{p-1}$ the last formula implies that $L_{p}\left(\mu_{\mathbf{z}}, s\right)$ has a zero at $s=0$ and

$$
\begin{equation*}
L_{p}^{\prime}\left(\mu_{\mathbf{z}}, 0\right)=-(\log \chi(\gamma)) H_{0}(0) \tag{23}
\end{equation*}
$$

On the other hand, by Proposition 2.2.2

$$
\begin{align*}
& H_{0}(0)=\mathbf{z}_{0} \cup\left(\operatorname{pr}_{0} F\right)=\tilde{\mathbf{z}}_{0} \cup \delta_{D}(d)=\Gamma(h)\left(1-\frac{1}{p}\right)^{-1}(\log \chi(\gamma))^{-1}\left(\tilde{\mathbf{z}}_{0} \cup i_{c}(d)\right)=  \tag{24}\\
& =-\Gamma(h)\left(1-\frac{1}{p}\right)^{-1}(\log \chi(\gamma))^{-1} a .
\end{align*}
$$

From (22), (23) and (24) we obtain that

$$
L_{p}^{\prime}\left(\mu_{\mathbf{z}}, 0\right)=\Gamma(h)\left(1-\frac{1}{p}\right)^{-1} a=\ell(V, D) \Gamma(h)\left(1-\frac{1}{p}\right)^{-1}\left[d_{\alpha}, \exp _{V^{*}(1)}^{*}\left(\mathbf{z}_{0}\right)\right]_{V}
$$

and the Proposition is proved.

## §3. Trivial zeros of Dirichlet $L$-functions

3.1. Dirichlet $L$-functions. Let $\eta:(\mathbb{Z} / N \mathbb{Z})^{*} \rightarrow \mathbb{C}^{*}$ be a Dirichlet character of conductor $N$. We fix a primitive $N$-th root of unity $\zeta_{N}$ and set $\tau(\eta)=\sum_{a \bmod N} \eta(a) \zeta_{N}^{a}$. The Dirichlet $L$-function

$$
L(\eta, s)=\sum_{n=1}^{\infty} \frac{\eta(n)}{n^{s}}, \quad \operatorname{Re}(s)>1
$$

has a meromorphic continuation on the whole complex plane and satisfies the functional equation

$$
\left(\frac{N}{\pi}\right)^{s / 2} \Gamma\left(\frac{s+\delta_{\eta}}{2}\right) L(\eta, s)=W_{\eta}\left(\frac{N}{\pi}\right)^{(1-s) / 2} \Gamma\left(\frac{1-s+\delta_{\eta}}{2}\right) L(\bar{\eta}, 1-s)
$$

where $W_{\eta}=i^{-\delta_{\eta}} N^{-1 / 2} \tau(\eta)$ and $\delta_{\eta}=\frac{1-\eta(-1)}{2}$. From now until the end of this $\S$ we assume that $\eta$ is not trivial. For any $j \geqslant 0$ the special value $L(\eta,-j)$ is the algebraic integer given by

$$
\begin{equation*}
L(\eta,-j)=\frac{d^{j} F_{\eta}(0)}{d t^{j}} \tag{25}
\end{equation*}
$$

where

$$
F_{\eta}(t)=\frac{1}{\tau\left(\eta^{-1}\right)} \sum_{a \bmod N} \frac{\eta^{-1}(a)}{1-\zeta_{N}^{a} e^{t}}
$$

(see for example [PR3, proof of Proposition 3.1.4] ). In particular

$$
\begin{equation*}
L(\eta, 0)=\frac{1}{\tau\left(\eta^{-1}\right)} \sum_{a} \frac{\eta^{-1}(a)}{1-\zeta_{N}^{a}} . \tag{26}
\end{equation*}
$$

Moreover $L(\eta,-j)=0$ if and only if $j \equiv \delta_{\eta}(\bmod 2)$.
Let $p$ be a prime number such that $(p, N)=1$. We fix a finite extension $L$ of $\mathbb{Q}_{p}$ containing the values of all Dirichlet characters $\eta$ of conductor $N$. The power series

$$
\mathscr{A}_{\mu_{\eta}}(X)=-\frac{1}{\tau\left(\eta^{-1}\right)} \sum_{a \bmod N}\left(\frac{\eta^{-1}(a)}{(1+X) \zeta_{N}^{a}-1}-\frac{\eta^{-1}(a)}{(1+X)^{p} \zeta_{N}^{p a}-1}\right)
$$

lies in $O_{L}[[X]]^{\psi=0}$ and therefore can be viewed as the Amice transform of a unique mesure $\mu_{\eta}$ on $\mathbb{Z}_{p}^{*}$. The $p$-adic $L$-functions associated to $\eta$ are defined to be

$$
L_{p}\left(\eta \omega^{m}, s\right)=\int_{\mathbb{Z}_{p}^{*}} \omega^{m-1}(x)\langle x\rangle^{-s} \mu_{\eta}(x), \quad 0 \leqslant m \leqslant p-2 .
$$

From (6) and (25) it follows that these functions satisfy the following interpolation property (Iwasawa theorem)

$$
L_{p}\left(\eta \omega^{m}, 1-j\right)=\left(1-\left(\eta \omega^{m-j}\right)(p) p^{1-j}\right) L\left(\eta \omega^{m-j}, 1-j\right) \quad j \geqslant 1 .
$$

Note that the Euler factor $1-\left(\eta \omega^{m-n}\right)(p) p^{1-j}$ vanishes if $m=j=1$ and $\eta(p)=1$ and that $L(\eta, 0)$ does not vanish if and only if $\eta$ is odd i.e. $\eta(-1)=-1$.
3.2. $p$-adic representations associated to Dirichlet characters. We continue to assume that $(p, N)=1$. Set $F=\mathbb{Q}\left(\zeta_{N}\right), G=\operatorname{Gal}(F / \mathbb{Q})$ and let $\rho: G \simeq(\mathbb{Z} / N \mathbb{Z})^{*}$ denote the canonical isomorphism normalized by $g\left(\zeta_{N}\right)=\zeta_{N}^{\rho(g)^{-1}}$. Fix a finite extension $L / \mathbb{Q}_{p}$ containing the values of all Dirichlet characters modulo $N$. If $\eta$ is such a character, we identify $\eta$ with the character $\psi \circ \rho$ of $G$ and denote by $L(\psi)$ the associated one-dimensional Galois representation. Let $S$ denote the set of primes dividing $N$.

Assume that $\eta$ is a non trivial character of conductor $N$. We need the following well known results about the Galois cohomology of $L(\eta)$.
i) $H^{*}\left(\mathbb{Q}_{l}, L(\eta)\right)=H^{*}\left(\mathbb{Q}_{l}, L\left(\chi \eta^{-1}\right)\right)=0$ for $l \in S$.
ii) $H_{f}^{1}(\mathbb{Q}, L(\eta))=0$ and $H_{f}^{1}\left(\mathbb{Q}, L\left(\chi \eta^{-1}\right)\right) \simeq\left(O_{F}^{*} \otimes_{\mathbb{Z}} L\right)^{(\eta)}$. In particular, $H_{f}^{1}\left(\mathbb{Q}, L\left(\chi \eta^{-1}\right)\right)=0$ if $\eta$ is odd.
iii) The restriction of $L(\eta)$ on the decomposition group at $p$ is crystalline. More precisely, $\varphi$ acts on $\mathbf{D}_{\text {cris }}(L(\eta))$ as multiplication by $\eta(p)$ and the unique Hodge-Tate weight of $L(\eta)$ is 0 .

Note that $H^{0}\left(\mathbb{Q}_{l}, L(\eta)\right)=0$ if $l \mid N$ because in this case the inertia group acts non-trivially on $L(\eta)$. Together with Poincaré duality and the Euler characteristic formula this gives i). To prove ii) it is enough to remark that $H_{f}^{1}\left(F, \mathbb{Q}_{p}(1)\right) \simeq O_{F}^{*} \hat{\otimes} \mathbb{Q}_{p}$ (see for example [Ka1, $\left.\left.\S 5\right]\right)$. Finally iii) follows immediately from the definition of $\mathbf{D}_{\text {cris }}$.

Assume now that $\eta$ is odd and $\eta(p)=1$. Then $\varphi$ acts on $\mathbf{D}_{\text {cris }}\left(L\left(\chi \eta^{-1}\right)\right)$ as multiplication by $p^{-1}$ and $D=\mathbf{D}_{\text {cris }}\left(L\left(\chi \eta^{-1}\right)\right)$ satisfies the conditions 1-4) from Section 2.1.1. The isomorphism (9) writes

$$
H_{S}^{1}\left(\mathbb{Q}, L\left(\chi \eta^{-1}\right)\right) \simeq \frac{H^{1}\left(\mathbb{Q}_{p}, L(\chi)\right)}{H_{f}^{1}\left(\mathbb{Q}_{p}, L(\chi)\right)} .
$$

### 3.3. Trivial zeros.

3.3.1. Cyclotomic units. Set $F_{n}=F\left(\zeta_{p^{n}}\right)$. The collection $\mathbf{z}_{\text {cycl }}=\left(1-\zeta_{N}^{p^{-n}} \zeta_{p^{n}}\right)_{n \geqslant 1}$ form a norm compartible system of units which can be viewed as an element of $H_{\mathrm{Iw}, S}^{1}(F, L(\chi))$ using Kummer maps $F_{n}^{*} \rightarrow H_{S}^{1}\left(F_{n}, L(\chi)\right)$. Twisting by $\varepsilon^{-1}$ we obtain an element $\mathbf{z}_{\mathrm{cycl}}(-1) \in H_{\mathrm{Iw}, S}^{1}(F, L)$. Shapiro's lemma gives an isomorphism of $G$-modules $H_{\mathrm{Iw}}^{1}\left(F \otimes \mathbb{Q}_{p}, L\right) \simeq H_{\mathrm{IW}}^{1}\left(\mathbb{Q}_{p}, L[G]^{\iota}\right)$. Let $e_{\eta}=\frac{1}{|G|} \sum_{g \in G} \eta^{-1}(g) g$. Since $e_{\eta} L[G]^{\iota}=L e_{\eta^{-1}}$ is isomorphic to $L\left(\eta^{-1}\right)$ we have

$$
e_{\eta} H_{\mathrm{Iw}}^{1}\left(F \otimes \mathbb{Q}_{p}, L\right) \simeq H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, L\left(\eta^{-1}\right)\right) .
$$

Moreover $\mathbf{D}_{\text {cris }}(L[G]) \simeq(L[G] \otimes F)^{G} \simeq L \otimes F$. The isomorphism $\mathbb{Q}[G] \simeq F$ defined by $\lambda \mapsto \lambda\left(\zeta_{N}\right)$ induces an isomorphism $\mathbf{D}_{\text {cris }}(L[G]) \simeq L[G]$ and therefore we can consider $e_{\eta}$ as a basis of $\mathbf{D}_{\text {cris }}\left(L\left(\eta^{-1}\right)\right)$. Let $\mathbf{z}_{\mathrm{cycl}}^{\eta}(-1)$ denote the image of $\mathbf{z}_{\mathrm{cycl}}(-1)$ in $H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, L\left(\eta^{-1}\right)\right)$. We need the following properties of these elements:

1) Relation to the complex L-function. Let $\mathbf{z}_{\text {cycl }}^{\eta^{-1}}(-1)_{0}$ denote the projection of $\mathbf{z}_{\text {cycl }}^{\eta^{-1}}(-1)$ on $H^{1}\left(\mathbb{Q}_{p}, L(\eta)\right)$. Then

$$
\exp _{L(\eta)}^{*}\left(\mathbf{z}_{\mathrm{cycl}}^{\eta^{-1}}(-1)_{0}\right)=-\left(1-\frac{\eta^{-1}(p)}{p}\right) L(\eta, 0) e_{\eta^{-1}}
$$

2) Relation to the p-adic L-function. Let $e_{\eta^{-1}}^{*} \in \mathbf{D}_{\text {cris }}\left(L\left(\chi \eta^{-1}\right)\right)$ be the basis which is dual to $e_{\eta^{-1}}$ and let $\mathfrak{L}_{L(\eta), 0}^{(\varepsilon)}: H_{\mathrm{Iw}}^{1}\left(\mathbb{Q}_{p}, L(\eta)\right) \rightarrow \mathscr{H}(\Gamma)$ denote the associated logarithmic map. Then

$$
\mathfrak{L}_{L(\eta), 0}^{\varepsilon}\left(\mathbf{z}_{\mathrm{cycl}}^{\eta^{-1}}(-1)\right)=-\mathbf{M}\left(\mu_{\eta}\right)
$$

We remark that 1) follows from the explicit reciprocity law of Iwasawa [Iw] together with (26). See also [Ka1, Theorem 5.12] and [HK, Corollary 3.2.7] where a more general statement is proved using the explicit reciprocity law for $\mathbb{Q}_{p}(r)$. The statement 2) is a reformulation of Coleman's construction of $p$-adic $L$-functions in terms of the large logarithmic map [PR3, Proposition 3.1.4].
Theorem 3.3.2. Let $\eta$ be an odd character of conductor $N$. Assume that $p$ is a prime odd number such that $p \nmid N$ and $\eta(p)=1$. Then

$$
L^{\prime}(\eta \omega, 0)=-\mathscr{L}(\eta) L(\eta, 0)
$$

where $\mathscr{L}(\eta)$ is the invariant defined by (3).
Proof. It is easy to see that $\mathscr{L}(\eta)$ coincides with $\ell\left(L\left(\chi \eta^{-1}\right), D\right)$. Applying Proposition 2.3.4 to $V=$ $L\left(\chi \eta^{-1}\right), D=\mathbf{D}_{\text {cris }}\left(L\left(\chi \eta^{-1}\right)\right)$ and $\mathbf{z}=\mathbf{z}_{\text {cycl }}^{\eta^{-1}}(-1)$ and taking into account 1-2) above we obtain that

$$
L_{p}^{\prime}(\eta \omega, 0)=L_{p}^{\prime}\left(\mu_{z}, 0\right)=\ell\left(L\left(\chi \eta^{-1}\right), D\right)\left(1-\frac{1}{p}\right)^{-1}\left[e_{\eta^{-1}}^{*}, \exp _{L(\eta)}^{*}\left(\mathbf{z}_{0}\right)\right]=-\mathscr{L}(\eta) L(\eta, 0)
$$

and the Theorem is proved.

## §4. Trivial zeros of modular forms

## 4.1. $p$-adic $L$-functions.

4.1.1. Construction of $p$-adic $L$-functions (see $[\mathrm{AV}],[\mathrm{Mn}],[\mathrm{Vi}],[\mathrm{MTT}])$. Let $f=\sum_{n=1}^{\infty} a_{n} q^{n}$ be a normalized newform on $\Gamma_{0}(N)$ of weight $k$ and character $\varepsilon$. The complex $L$-function $L(f, s)=\sum_{n=1}^{\infty} a_{n} n^{-s}$ decomposes into an Euler product

$$
L(f, s)=\prod_{p} E_{p}\left(f, p^{-s}\right)^{-1}
$$

with $E_{p}(f, X)=1-a_{p} X+\varepsilon(p) p^{k-1} X^{2}$. Let $p>2$ be a prime such that the Euler factor $E_{p}(f, X)$ is not equal to 1 and let $\alpha \in \overline{\mathbb{Q}}_{p}$ be a root of the polynomial $X^{2}-a_{p} X+\varepsilon(p) p^{k-1}$. Assume that $\alpha$ is not critical i.e. that $v_{p}(\alpha)<k-1$. Manin-Vishik [Mn], [Vi], and independently Amice-Velu [AV] proved that there exists a unique distribution $\mu_{f, \alpha}$ on $\hat{\mathbb{Z}}^{(p)}$ of order $v_{p}(\alpha)$ such that for any Dirichlet caracter $\eta$ of conductor $M$ prime to $p$ and any Dirichlet character $\xi$ of conductor $p^{m}$

$$
\int_{\hat{\mathbb{Z}}(p)} \eta(x) \xi(x) x^{j-1} \mu_{f, \alpha}(x)= \begin{cases}\left(1-\frac{\bar{\eta}(p) p^{j-1}}{\alpha}\right)\left(1-\frac{\beta \eta(p)}{p^{j}}\right) \widetilde{L}(f, \eta, j) & \text { if } 1 \leqslant j \leqslant k-1 \text { and } m=0, \\ \frac{p^{m j} \bar{\eta}\left(p^{m}\right)}{\alpha^{m} \tau(\bar{\xi})} \widetilde{L}\left(f, \eta \xi^{-1}, j\right) & \text { if } 1 \leqslant j \leqslant k-1 \text { and } m \geqslant 1\end{cases}
$$

where $\tau(\bar{\xi})=\sum_{a=1}^{p^{m}-1} \bar{\xi}(a) \zeta_{p^{m}}^{a}$ and $\widetilde{L}(f, \eta, j)$ is the algebraic part of $L(f, \eta, j)$ (see (1)). For us it will be more convenient to work with the distribution $\lambda_{f, \alpha}=x^{-1} \mu_{f, \alpha}$. The $p$-adic $L$-functions associated to $\eta:(\mathbb{Z} / M \mathbb{Z})^{*} \rightarrow \overline{\mathbb{Q}}_{p}^{*}$ are defined by ${ }^{3}$

$$
\begin{equation*}
L_{p, \alpha}\left(f, \eta \omega^{m}, s\right)=\int_{\hat{\mathbb{Z}}(p)} \eta \omega^{m}(x)\langle x\rangle^{s} \lambda_{f, \alpha}(x) \quad 0 \leqslant m \leqslant p-2 . \tag{27}
\end{equation*}
$$

${ }^{3}$ Our $L_{p, \alpha}\left(f, \eta \omega^{m}, s\right)$ coincides with $L_{p}\left(f, \alpha, \bar{\eta} \omega^{m-1}, s-1\right)$ of [MTT]

It is easy to see that $L_{p, \alpha}\left(f, \eta \omega^{m}, s\right)$ is a $p$-adic analytic function which satisfies the following interpolation property

$$
\begin{equation*}
L_{p, \alpha}\left(f, \eta \omega^{m}, j\right)=\mathcal{E}_{\alpha}\left(f, \eta \omega^{m}, j\right) \widetilde{L}\left(f, \eta \omega^{j-m}, j\right), \quad 1 \leqslant j \leqslant k-1 \tag{28}
\end{equation*}
$$

where

$$
\mathcal{E}_{\alpha}\left(f, \eta \omega^{m}, j\right)= \begin{cases}\left(1-\frac{\bar{\eta}(p) p^{j-1}}{\alpha}\right)\left(1-\frac{\eta(p) \varepsilon(p) p^{k-j-1}}{\alpha}\right) & \text { if } j \equiv m(\bmod p-1)  \tag{29}\\ \frac{\bar{\eta}(p) p^{j}}{\alpha \tau\left(\omega^{j-m}\right)} & \text { if } j \not \equiv m(\bmod p-1)\end{cases}
$$

4.1.2. $p$-adic representations associated to modular forms. For each prime $p$ Deligne [D1] constructed a $p$-adic representation

$$
\rho_{f}: \operatorname{Gal}(\overline{\mathbb{Q}} / \mathbb{Q}) \rightarrow \operatorname{GL}\left(W_{f}\right)
$$

with coefficients in a finite extension $L$ of $\mathbb{Q}_{p}$. This representation has the following properties:
i) $\operatorname{det} \rho_{f}$ is isomorphic to $\varepsilon \chi^{k-1}$ where $\chi$ is the cyclotomic character.
ii) If $l \nmid N p$ then the restriction of $\rho_{f}$ on the decomposition group at $l$ is unramified and

$$
\operatorname{det}\left(1-\operatorname{Fr}_{l} X \mid W_{f}\right)=1-a_{l} X+\varepsilon(l) l^{k-1} X^{2}
$$

(Deligne-Langlands-Carayol theorem [Ca], [La]).
iii) The restriction of $\rho_{f}$ on the decomposition group at $p$ is potentially semistable with HodgeTate weights $(0, k-1)$ [Fa1]. It is crystalline if $p \nmid N$ and semistable non-crystalline if $p \| N$ and $(p, \operatorname{cond}(\varepsilon))=1$. If $p \mid N$ and $\operatorname{ord}_{p}(N)=\operatorname{ord}_{p}(\operatorname{cond}(\varepsilon))$ the restriction of $\rho_{f}$ on the decomposition group at $p$ is potentially crystalline and $\mathbf{D}_{\text {cris }}\left(W_{f}\right)=\mathbf{D}_{\text {pcris }}\left(W_{f}\right)^{\operatorname{Gal}\left(\overline{\mathbb{Q}}_{p} / \mathbb{Q}_{p}\right)}$ is one-dimensional. In all cases

$$
\operatorname{det}\left(1-\varphi X \mid \mathbf{D}_{\text {cris }}\left(W_{f}\right)\right)=1-a_{p} X+\varepsilon(p) p^{k-1} X^{2}
$$

(Saito theorem [Sa], see also [Fa2], [Ts]).
4.1.3. Trivial zeros (see $[\mathrm{MTT}])$. We say that $L_{p, \alpha}\left(f, \eta \omega^{m}, s\right)$ has a trivial zero at $s=j$ if

$$
L\left(f, \eta \omega^{j-m}, j\right) \neq 0 \quad \text { and } \quad \mathcal{E}_{\alpha}\left(f, \eta \omega^{m}, j\right)=0 .
$$

From (29) it is not difficult to deduce that this occurs in the following three cases [MTT, §15]:

- The semistable case: $p \| N, k$ is even and $(p, \operatorname{cond}(\varepsilon))=1$. Thus $\varepsilon(p)=0, E_{p}(f, X)=1-a_{p} X$ and $a_{p}$ is the unique non-critical root of $X^{2}-a_{p} X$. The restriction of $W_{f}$ on the decomposition group at $p$ is semistable and the eigenvalues of $\varphi$ acting on $\mathbf{D}_{\text {st }}\left(W_{f}\right)$ are $\alpha=a_{p}$ and $\beta=p \alpha$. The module $\mathbf{D}_{\text {st }}\left(W_{f}\right)$ has a basis $\left\{e_{\alpha}, e_{\beta}\right\}$ such that $\varphi\left(e_{\alpha}\right)=a_{p} e_{\alpha}, \varphi\left(e_{\beta}\right)=\beta e_{\beta}$ and $N\left(e_{\beta}\right)=e_{\alpha}$. Moreover $\mathbf{D}_{\text {cris }}\left(W_{f}\right)=L e_{\alpha}$. Let $\tilde{\varepsilon}$ be the primitive character associated to $\varepsilon$. Then $\tilde{\varepsilon}(p) \neq 0$ and $a_{p}^{2}=\tilde{\varepsilon}(p) p^{k-2}$ [Li, Theorem 3]. Write $a_{p}=\xi p^{k / 2-1}$ where $\xi$ is a root of unity. Then $\mathcal{E}_{\alpha}\left(f, \eta \omega^{m}, j\right)=0$ if and only if $j=k / 2, m \equiv k / 2$ $\bmod (p-1)$ and $\bar{\eta}(p)=\xi$. Therefore the $p$-adic $L$-function $L_{p, \alpha}\left(f, \eta \omega^{k / 2}, s\right)$ has a trivial zero at the central point $s=k / 2$ if and only if $\bar{\eta}(p)=\xi$.
- The crystalline case: $p \nmid N$. The restriction of $W_{f}$ on the decomposition group at $p$ is crystalline and by Deligne [D2] one has $|\alpha|=p^{(k-1) / 2}$. Write $\alpha=\xi p^{\frac{k-1}{2}}$ with $|\xi|=1$. Then $\mathcal{E}_{\alpha}\left(f, \eta \omega^{m}, j\right)$ vanishes if and
only if $m \equiv j(\bmod p-1), k$ is odd, and either $j=\frac{k+1}{2}$ and $\bar{\eta}(p)=\xi$ or $j=\frac{k-1}{2}$ and $\eta(p) \varepsilon(p)=\xi$. The $p$-adic $L$-function $L_{p, \alpha}\left(f, \eta \omega^{\frac{k+1}{2}}, s\right)$ has a trivial zero at the near-central point $s=\frac{k+1}{2}$ if and only if $\alpha=\bar{\eta}(p) p^{\frac{k-1}{2}}$ and $L_{p, \alpha}\left(f, \eta \omega^{\frac{k-1}{2}}, s\right)$ has a trivial zero at $s=\frac{k-1}{2}$ if and only if $\alpha=\eta(p) \varepsilon(p) p^{\frac{k-1}{2}}$.
- The potentially crystalline case: $p \mid N$ and $\operatorname{ord}_{p}(N)=\operatorname{ord}_{p}(\operatorname{cond}(\varepsilon))$. One has $E_{p}(f, X)=1-a_{p} X$ and $\alpha=a_{p}$ is the unique non-critical root of $X^{2}-a_{p} X$. Moreover $\tilde{\varepsilon}(p)=0$ and it can be shown that $\left|a_{p}\right|=p^{\frac{k-1}{2}}[\mathrm{O}],[\mathrm{Li}]$. The restriction of $W_{f}$ on the decomposition group at $p$ is potentially crystalline and $\mathbf{D}_{\text {cris }}\left(W_{f}\right)$ is a one-dimensional vector space on which $\varphi$ acts as multiplication by $a_{p}$. The factor $\mathcal{E}_{\alpha}\left(f, \eta \omega^{m}, j\right)$ vanishes if and only if $k$ is odd, $j=m=\frac{k+1}{2}$ and $a_{p}=\bar{\eta}(p) p^{\frac{k-1}{2}}$. The $p$-adic $L$-function $L_{\alpha, p}\left(f, \eta \omega^{\frac{k+1}{2}}, s\right)$ has a trivial zero at the near-central point $s=\frac{k+1}{2}$ if and only if $a_{p}=\eta(p) p^{\frac{k-1}{2}}$.

If $\eta$ is a Dirichlet character of conductor $M$, the twisted modular form $f_{\eta}=\sum_{n=1}^{\infty} \eta(n) a_{n} q^{n}$ is not necessarily primitive, but there exists a unique normalized newform $f \otimes \eta$ such that

$$
L(f, \eta, s)=L(f \otimes \eta, s) \prod_{l \mid M} E_{l}\left(f \otimes \eta, l^{-s}\right)
$$

(see for example [AL]). Write $L(f \otimes \eta, s)=\sum_{n=1}^{\infty} \frac{a_{\eta, n}}{n^{s}}$. If $p \nmid M$, the Euler factors at $p$ of $L_{M}(f \otimes \eta, s)$ and $L(f, \eta, s)$ coincide and $\alpha_{\eta}=\alpha \eta(p)$ is a root of $X^{2}-a_{\eta, p} X+\varepsilon(p) \eta^{2}(p) p^{k-1}$. It is easy to see that $\mathcal{E}_{\alpha_{\eta}}\left(f_{\eta}, \omega^{m}, j\right)=\mathcal{E}_{\alpha}\left(f, \eta \omega^{m}, j\right)$ and from the interpolation formula (28) it follows immediately that the behavior of $L_{p, \alpha}\left(f, \eta \omega^{m}, s\right)$ and $L_{p, \alpha_{\eta}}\left(f \otimes \eta, \omega^{m}, s\right)$ is essentially the same. Therefore the general case reduces to the case of the trivial character $\eta$.

### 4.2. Selmer groups and $\ell$-invariants of modular forms.

4.2.1. The Selmer group. From now until the end of this $\S$ we assume that $L_{p, \alpha}\left(f, \omega^{k_{0}}, s\right)$ has a trivial zero at $k_{0}$. Thus $k_{0}=k / 2$ in the semistable case and $k_{0}=\frac{k \pm 1}{2}$ in the crystalline or potentially crystalline case. Set $V_{f}=W_{f}\left(k_{0}\right)$. Let $f^{*}$ denote the complex conjugation of $f$ i.e. $f^{*}=\sum_{n=1}^{\infty} \bar{a}_{n} q^{n}$. The canonical pairing $W_{f} \times W_{f^{*}} \rightarrow L(1-k)$ induces an isomorphism $W_{f^{*}}\left(k-k_{0}\right) \simeq V_{f}^{*}(1)$. We need the following basic results about the Galois cohomology of $V_{f}$ :
i) $H^{0}\left(\mathbb{Q}_{p}, V_{f}\right)=H^{0}\left(\mathbb{Q}_{p}, V_{f}^{*}(1)\right)=0$ and $\operatorname{dim}_{L} H^{1}\left(\mathbb{Q}_{p}, V_{f}\right)=\operatorname{dim}_{L} H^{1}\left(\mathbb{Q}_{p}, V_{f}^{*}(1)\right)=2$.
ii) $H_{f}^{1}\left(\mathbb{Q}_{p}, V_{f}\right)$ and $H_{f}^{1}\left(\mathbb{Q}_{p}, V_{f}^{*}(1)\right)$ are one-dimensional $L$-vector spaces.
iii) $H_{f}^{1}\left(\mathbb{Q}, V_{f}\right)=H_{f}^{1}\left(\mathbb{Q}, V_{f}^{*}(1)\right)=0$.

We remark that using the fact that the Hodge-Tate weights of $W_{f}$ are 0 and $k-1$ and the eigenvalues of $\varphi$ on $\mathbf{D}_{\text {cris }}\left(W_{f}\right)$ have absolute value $p^{(k-1) / 2}$ (respectively $p^{k / 2}$ ) in the crystalline and potentially crystalline case (respectively in the semistable case) one deduce that $H^{0}\left(\mathbb{Q}_{p}, W_{f}(m)\right)=0$ for all $1 \leqslant$ $m \leqslant k-1$ (see [Ka2, Proposition 14.12 and Section 13.3]). Applying Poincaré duality and the Euler characteristic formula we obtain i). Next ii) follows from i) together with the formula

$$
\operatorname{dim}_{L} H_{f}^{1}\left(\mathbb{Q}_{p}, V_{f}\right)=\operatorname{dim}_{L} t_{V_{f}}(L)+\operatorname{dim}_{L} H^{0}\left(\mathbb{Q}_{p}, V_{f}\right) .
$$

Finally iii) is a deep result of Kato [Ka2, Theorem 14.2]. Note that in the semistable case we assume that $L(f, k / 2) \neq 0$.

From i-iii) above it follows that $V_{f}$ satisfies the conditions 1-3) of Section 2.2.1. Assume that $k_{0} \geqslant \frac{k+1}{2}$. This holds automatically in the semistable ( $k_{0}=k / 2$ ) and potentially crystalline ( $k_{0}=\frac{k+1}{2}$ ) cases. In the crystalline case $\alpha^{*}=\varepsilon^{-1}(p) \alpha$ is a root of $1-\bar{a}_{p} X+\varepsilon^{-1}(p) p^{k-1} X^{2}$ and using the functional equation for $p$-adic $L$-functions one can reduce the study of $L_{p, \alpha}\left(f, \omega^{k_{0}}, s\right)$ at $s=\frac{k-1}{2}$ to the study of $L_{p, \alpha^{*}}\left(f^{*}, \omega^{k_{0}+1}, s\right)$ at $s=\frac{k+1}{2}$.

Lemma 4.2.2. Assume that $L_{p, \alpha}\left(f, \omega^{k_{0}}, s\right)$ has a trivial zero on the right of the central point (i.e. $\left.k_{0} \geqslant k / 2\right)$. Then $D_{\alpha}=\mathbf{D}_{\text {cris }}\left(V_{f}\right)^{\varphi=p^{-1}}$ is a one dimentional L-vector space which satisfies one of the conditions $a-b$ ) of Proposition 2.1.2.
Proof. From 4.1.2 it follows that $\alpha p^{-k_{0}}=p^{-1}$ is an eigenvalue of $\varphi$ acting on $\mathbf{D}_{\text {cris }}\left(V_{f}\right)$. Thus $\operatorname{dim}_{L} D_{\alpha} \geqslant$ 1. If $\operatorname{dim}_{L} D_{\alpha}=2$ then $V_{f}$ would be crystalline and $\varphi$ would act on $\mathbf{D}_{\text {cris }}\left(V_{f}\right)$ as multiplication by $p^{-1}$. This contadicts the weak admissibility of $\mathbf{D}_{\text {cris }}\left(V_{f}\right)$. Finally $D_{\alpha}$ satisfies a) in the crystalline and potentially crystalline cases and $b$ ) in the semistable case.
4.2.3. The $\ell$-invariant of modular forms. From Lemma 4.2 .2 it follows that if $L_{p, \alpha}\left(f, \omega^{k_{0}}, s\right)$ has a trivial zero at $k_{0} \geqslant k / 2$ the $\ell$-invariant $\ell\left(V_{f}, D_{\alpha}\right)$ is well defined. To simplify notation we will denote it by $\ell_{\alpha}(f)$. The general definition of the $\ell$-invariant can be made more explicit in the case of modular forms.

- The semistable case. Let $\left\{e_{\alpha}, e_{\beta}\right\}$ denote the basis of $\mathbf{D}_{\text {st }}\left(W_{f}\right)$ as in 4.1.3. In [Ben2, Proposition 2.3.7] it is proved that

$$
\begin{equation*}
\ell_{\alpha}(f)=\mathscr{L}_{\mathrm{FM}}(f) \tag{30}
\end{equation*}
$$

where $\mathscr{L}_{\mathrm{FM}}(f)$ is the Fontaine-Mazur invariant $[\mathrm{Mr}]$ which is defined as the unique element of $L$ such that

$$
e_{\beta}+\mathscr{L}_{\mathrm{FM}}(f) e_{\alpha} \in \mathrm{Fil}^{k-1} \mathbf{D}_{\mathrm{st}}\left(W_{f}\right)
$$

- The crystalline and potentially crystalline cases. The $(\varphi, \Gamma)$-module $\mathbf{D}_{\mathrm{rig}}^{\dagger}\left(V_{f}\right) \cap\left(D_{\alpha} \otimes_{L} \mathscr{R}_{L}[1 / t]\right)$ is isomorphic to $\mathscr{R}_{L}(\delta)$ with $\delta(x)=|x| x^{\frac{k+1}{2}}$ and the exact sequence (11) writes

$$
0 \rightarrow \mathscr{R}_{L}(\delta) \rightarrow \mathbf{D}_{\mathrm{rig}}^{\dagger}\left(V_{f}\right) \rightarrow \mathscr{R}_{L}\left(\delta^{\prime}\right) \rightarrow 0
$$

for some character $\delta^{\prime}: \mathbb{Q}_{p}^{*} \rightarrow L^{*}$. Since $\operatorname{dim}_{L} H^{1}\left(\mathscr{R}_{L}(\delta)\right)=2$ we have $H^{1}\left(\mathbb{Q}_{p}, V_{f}\right) \simeq H^{1}\left(\mathscr{R}_{L}(\delta)\right)$. Therefore $H_{D_{\alpha}}^{1}\left(V_{f}\right)=H_{f,\{p\}}^{1}\left(\mathbb{Q}, V_{f}\right)$ and $\mathscr{L}_{\alpha}(f)=\mathscr{L}\left(V_{f}, D_{\alpha}\right)$ is the slope of the image of the localization $\operatorname{map} H_{f,\{p\}}^{1}\left(\mathbb{Q}, V_{f}\right) \rightarrow H^{1}\left(\mathbb{Q}_{p}, V_{f}\right)$ under the canonical decomposition (6)

$$
H^{1}\left(\mathbb{Q}_{p}, V_{f}\right) \simeq H_{f}^{1}\left(\mathscr{R}_{L}(\delta)\right) \times H_{c}^{1}\left(\mathscr{R}_{L}(\delta)\right) .
$$

The formula (19) writes

$$
\begin{equation*}
\ell_{\alpha}(f)=-\mathscr{L}_{\alpha}(f) . \tag{31}
\end{equation*}
$$

### 4.3. The main result.

4.3.1. Kato's Euler systems. Using the theory of modular units Kato [Ka2] constructed an element $\mathbf{z}_{\mathrm{Kato}} \in H_{\mathrm{Iw}, S}^{1}\left(W_{f^{*}}\right)$ which is closely related to the complex and the $p$-adic $L$-functions via the BlochKato exponential map. The CM-case was considered before by Rubin [Ru]. Set

$$
\mathbf{z}_{\text {Kato }}(j)=\operatorname{Tw}_{j}^{\varepsilon}\left(\mathbf{z}_{\text {Kato }}\right) \in H_{\mathrm{Iw}, S}^{1}\left(W_{f^{*}}(j)\right)
$$

and denote by $\mathbf{z}_{\text {Kato }}(j)_{0}=\operatorname{pr}_{0}\left(\mathbf{z}_{\text {Kato }}(j)\right)$ the projection of $\mathbf{z}_{\mathrm{Kato}}(j)$ on $H_{S}^{1}\left(W_{f^{*}}(j)\right)$. The following statements are direct analogues of properties 1-2) of cyclotomic units from Section 3.3.1:

1) Relation to the complex L-function. One has

$$
\begin{equation*}
\exp _{W_{f^{*}(j)}}^{*}\left(\mathbf{z}_{\text {Kato }}(j)_{0}\right)=\Gamma(k-j)^{-1} E_{p}\left(f, p^{k-j}\right) \widetilde{L}(f, k-j) \omega_{j}^{*}, \quad 1 \leqslant j \leqslant k-1 \tag{32}
\end{equation*}
$$

for some canonical basis $\omega_{j}^{*}$ of $\operatorname{Fil}^{0} \mathbf{D}_{\text {cris }}\left(W_{f}^{*}(j)\right)\left[\mathrm{Ka} 2\right.$, Theorem 12.5]. Note that $\omega_{j+1}^{*}=\omega_{j}^{*} \otimes e_{1}$ where $e_{1}=\varepsilon^{-1} \otimes t$.
2) Relation to the p-adic L-function. Fix a generator $d_{\alpha}$ of $D_{\alpha}$. Let $\mathfrak{L}_{W_{f *}(k), 1}^{(\alpha),}$ denote the large logarithmic map $\mathfrak{L}_{W_{f^{*}(k), 1, \eta}^{(\varepsilon)}}$ associated to $\eta=d_{\alpha} \otimes e_{\frac{k+1}{2}} \in \mathbf{D}_{\text {cris }}\left(W_{f}\right)$. Then

$$
\begin{equation*}
\mathfrak{L}_{W_{f^{*}}(k), 1}^{(\alpha), \varepsilon}\left(\mathbf{z}_{\mathrm{Kato}}(k)\right)=\mathbf{M}\left(\lambda_{f, \alpha}\right)\left[d_{\alpha} \otimes e_{\frac{k+1}{2}}, \omega_{k}^{*}\right]_{W_{f}} \tag{33}
\end{equation*}
$$

[Ka2, Theorem 16.2].
We can now prove the main result of this paper.
Theorem 4.3.2. Let $f$ be a newform on $\Gamma_{0}(N)$ of character $\varepsilon$ and weight $k$ and let $p$ be an odd prime. Assume that the p-adic L-function $L_{p, \alpha}\left(f, \omega^{k_{0}}, s\right)$ has a trivial zero at $s=k_{0} \geqslant k / 2$. Then

$$
L_{p, \alpha}^{\prime}\left(f, \omega^{k_{0}}, k_{0}\right)=\ell_{\alpha}(f)\left(1-\frac{\varepsilon(p)}{p}\right) \widetilde{L}\left(f, k_{0}\right) .
$$

Proof. To simplify notation set $\mathbf{z}=\mathbf{z}_{\text {Kato }}\left(k-k_{0}\right)$. By Lemma 1.3.4 one has

$$
\mathfrak{L}_{V_{f}^{*}(1), 1-k_{0}}^{(\alpha), \varepsilon}(\mathbf{z})=\operatorname{Tw}_{k_{0}}\left(\mathfrak{L}_{W_{f^{*}}(k), 1}^{(\alpha), \varepsilon}\left(\mathbf{z}_{\text {Kato }}(k)\right)\right) .
$$

Let $\mu_{\mathbf{z}}$ be the distribution defined by $\mathbf{M}\left(\mu_{\mathbf{z}}\right)=\mathfrak{L}_{V_{f}^{\varepsilon_{f}}(1), 1-k_{0}}^{(\alpha),}(\mathbf{z})$. Then (33) gives

$$
\mathbf{M}\left(\mu_{\mathbf{z}}\right)=\operatorname{Tw}_{k_{0}}\left(\mathbf{M}\left(\lambda_{f, \alpha}\right)\right)\left[d_{\alpha} \otimes e_{k_{0}}, \omega_{k}^{*}\right]_{W_{f}}=\operatorname{Tw}_{k_{0}}\left(\mathbf{M}\left(\lambda_{f, \alpha}\right)\right)\left[d_{\alpha}, \omega_{k_{0}-1}^{*}\right]_{V_{f}}
$$

and from (8) and (27) it follows that

$$
L_{p}\left(\mu_{\mathbf{z}}, s\right)=L_{p, \alpha}\left(f, \omega^{k_{0}}, s+k_{0}\right)\left[d_{\alpha}, \omega_{k_{0}-1}^{*}\right]_{V_{f}} .
$$

Now, applying Proposition 2.2.4 we obtain

$$
\begin{equation*}
L_{p, \alpha}^{\prime}\left(f, \omega^{k_{0}}, k_{0}\right)\left[d_{\alpha}, \omega_{k_{0}-1}^{*}\right]_{V_{f}}=\ell_{\alpha}(f) \Gamma\left(k_{0}\right)\left(1-\frac{1}{p}\right)^{-1}\left[d_{\alpha}, \exp _{V_{f}^{*}(1)}^{*}\left(\mathbf{z}_{0}\right)\right]_{V_{f}} \tag{34}
\end{equation*}
$$

On the other hand, for $j=k-k_{0}$ the formula (32) gives

$$
\begin{equation*}
\exp _{V_{f}^{*}(1)}^{*}\left(\mathbf{z}_{0}\right)=\Gamma\left(k_{0}\right)^{-1} E_{p}\left(f, p^{k_{0}}\right) \widetilde{L}\left(f, k_{0}\right) \omega_{k_{0}-1}^{*} . \tag{35}
\end{equation*}
$$

Since $E_{p}\left(f, p^{k_{0}}\right)=\left(1-\frac{1}{p}\right)\left(1-\frac{\varepsilon(p)}{p}\right)$ and $\left[d_{\alpha}, \omega_{k_{0}-1}^{*}\right]_{V_{f}} \neq 0$, from (34) and (35) we obtain that

$$
L_{p, \alpha}^{\prime}\left(f, \omega^{k_{0}}, k_{0}\right)=\ell_{\alpha}(f)\left(1-\frac{\varepsilon(p)}{p}\right) \widetilde{L}\left(f, k_{0}\right)
$$

and the Theorem is proved.

Corollaries 4.3.3.1) In the semistable case $k$ is even and $\varepsilon(p)=0$. Theorem 4.3.2 together with (30) give the Mazur-Tate-Teitelbaum conjecture

$$
L_{p, \alpha}^{\prime}\left(f, \omega^{k / 2}, k / 2\right)=\mathscr{L}_{\mathrm{FM}}(f) \widetilde{L}(f, k / 2)
$$

and our proof can be seen as a revisiting of Kato-Kurihara-Tsuji approach using the theory of $(\varphi, \Gamma)$ modules.
2) In the crystalline and potentially crystalline cases Theorem 4.3.2 writes

$$
L_{p, \alpha}^{\prime}\left(f, \omega^{\frac{k+1}{2}}, \frac{k+1}{2}\right)=-\mathscr{L}_{\alpha}(f)\left(1-\frac{\varepsilon(p)}{p}\right) \widetilde{L}\left(f, \frac{k+1}{2}\right)
$$

(see (31)).

[^0]:    ${ }^{1}$ This construction was recently generalized to the critical case by Pollack-Stevens [PS] and Bellaiche [Bel]

[^1]:    ${ }^{2}$ Strictly speaking, in [Ben2] we define the $\ell$-invariant for $p$-adic representations which are semistable at $p$, but this construction can be generalized easily to cover the potentially crystalline case (see Section 2.1 below).
