SUMMARY

BMP and Wnt signaling pathways control essential cellular responses through activation of the transcription factors SMAD (BMP) and TCF (Wnt). Here, we show that regeneration of hematopoietic lineages following acute injury depends on the activation of each of these signaling pathways to induce expression of key blood genes. Both SMAD1 and TCF7L2 co-occupy sites with master regulators adjacent to hematopoietic genes. In addition, both SMAD1 and TCF7L2 follow the binding of the predominant lineage regulator during differentiation from multipotent hematopoietic progenitor cells to erythroid cells. Furthermore, induction of the myeloid lineage regulator C/EBP α in erythroid cells shifts binding of SMAD1 to sites newly occupied by C/EBP α , whereas expression of the erythroid regulator GATA1 directs SMAD1 loss on nonerythroid targets. We conclude that the regenerative response mediated by BMP and Wnt signaling pathways is coupled with the lineage master regulators to control the gene programs defining cellular identity.

INTRODUCTION

Cells sense and respond to their cellular environment through signal transduction pathways, which can deliver information to

the genome in the form of activated transcription factors. These factors tend to occupy specific genomic regions and associate with different coactivators and chromatin-remodeling complexes to direct their response. This occurs by either activating or repressing transcription or by changing the chromatin architecture, thus reforming the accessibility of certain genomic loci (Mosimann et al., 2009; Moustakas and Heldin, 2009). This combination of actions allows for the same signaling pathways to be used in multiple cellular environments eliciting different responses.

The BMP and Wnt signaling pathways are two highly conserved signaling pathways that interact during many developmental processes, ultimately through regulation of transcription via SMAD and TCF/LEF transcription factors (Clevers, 2006; Larsson and Karlsson, 2005; Staal and Luis, 2010). Both pathways participate in the formation of the hematopoietic system during development but appear to be expendable during adult steady-state hematopoiesis (Cheng et al., 2008; Goessling et al., 2009; Jeannot et al., 2008; Koch et al., 2008; Lengerke et al., 2008; McReynolds et al., 2007; Nostro et al., 2008; Singbrant et al., 2010; Tran et al., 2010). In both development and regeneration, hematopoietic stem cells (HSCs) divide and differentiate in response to cell-intrinsic and -extrinsic signals to produce all of the hematopoietic lineages. Here we show that the BMP and Wnt signaling pathways are critical for efficient regeneration of the adult hematopoietic system, as they are in development. Additionally, BMP and Wnt have been implicated in differentiation into erythroid and myeloid lineages. Specifically, in culture, BMP treatment can augment erythroid, megakaryocytic, and granulocytic-monocytic output of CD34⁺

progenitors (Detmer and Walker, 2002; Fuchs et al., 2002; Jeanpierre et al., 2008). Similarly, Wnt3a ligand can regulate the production of erythroid and myeloid cells from embryonic stem cells (ESCs) and myeloid progenitors from adult HSCs (Cheng et al., 2008; Nostro et al., 2008; Staal and Luis, 2010).

The underlying mechanism for BMP and Wnt regulation of regeneration and differentiation resides in the cell-type-specific targets of the SMAD and TCF transcription factors, respectively. Based on previous findings, SMAD and TCF proteins can couple with other transcription factors to regulate a small number of cell-specific genes (Clevers, 2006; Massagué et al., 2005; Mosimann et al., 2009). Signaling-mediated transcription factors have recently begun to be studied in a genome-wide manner, and these studies have revealed that Smad1 and Tcf711/Tcf3 can co-occupy target sites with the Oct4/Nanog/Sox2 transcriptional complex on pluripotency target genes in ESCs (Chen et al., 2008; Cole et al., 2008), and TCF7L2 can colocalize with CDX2 in colonic cells (Verzi et al., 2010). This led us to consider the possibility that BMP and Wnt signaling factors couple with distinct transcription factors important for lineage identity during hematopoietic regeneration and differentiation.

To determine how SMAD and TCF transcription factors select their targets in distinct lineages during regeneration and differentiation, we explored their genome-wide DNA binding in various hematopoietic environments across multiple species. Initially, cobinding of Smad1 with Gata2 at individual genes in regenerating progenitors was observed. Genome-wide analysis revealed that SMAD1 and TCF7L2 selectively bind in concert with cell-specific master regulators at lineage-distinctive genes in erythroid and myeloid cell populations. In addition, the expression of a myeloid master regulator in erythroid cells is sufficient to redirect a fraction of Smad1 binding. During differentiation, the binding of signaling factors shifts from genes of multiple hematopoietic lineages in progenitor cells to genes specific for differentiated cells guided by the dominant lineage factor. Together, these data support a mechanism by which lineage regulators direct SMAD and TCF proteins to tissue-specific enhancers. The selective use of these pathways during regeneration suggests that coordinated binding of SMAD1 and TCF7L2 with lineage-restricted regulators is the underlying mechanism for BMP and Wnt effects during hematopoietic differentiation and regeneration.

RESULTS

Wnt and BMP Play Essential Roles in Hematopoietic Regeneration

Wnt and BMP signaling are required during hematopoietic development, but it is unclear whether either pathway is necessary for adult hematopoietic regeneration. A zebrafish model was used to determine whether Wnt or BMP signaling is necessary during this process. Adult zebrafish were sublethally irradiated, and recovery of whole kidney marrow (WKM) cells was monitored by flow cytometry to identify precursor populations that are the first detectable sign of hematopoietic recovery (Traver et al., 2004) (Figure 1A). Stimulation of the Wnt signaling pathway using a heat shock-inducible Wnt8 ligand (Weidinger et al., 2005), or treatment with the GSK3 chemical inhibitor BIO, resulted in an

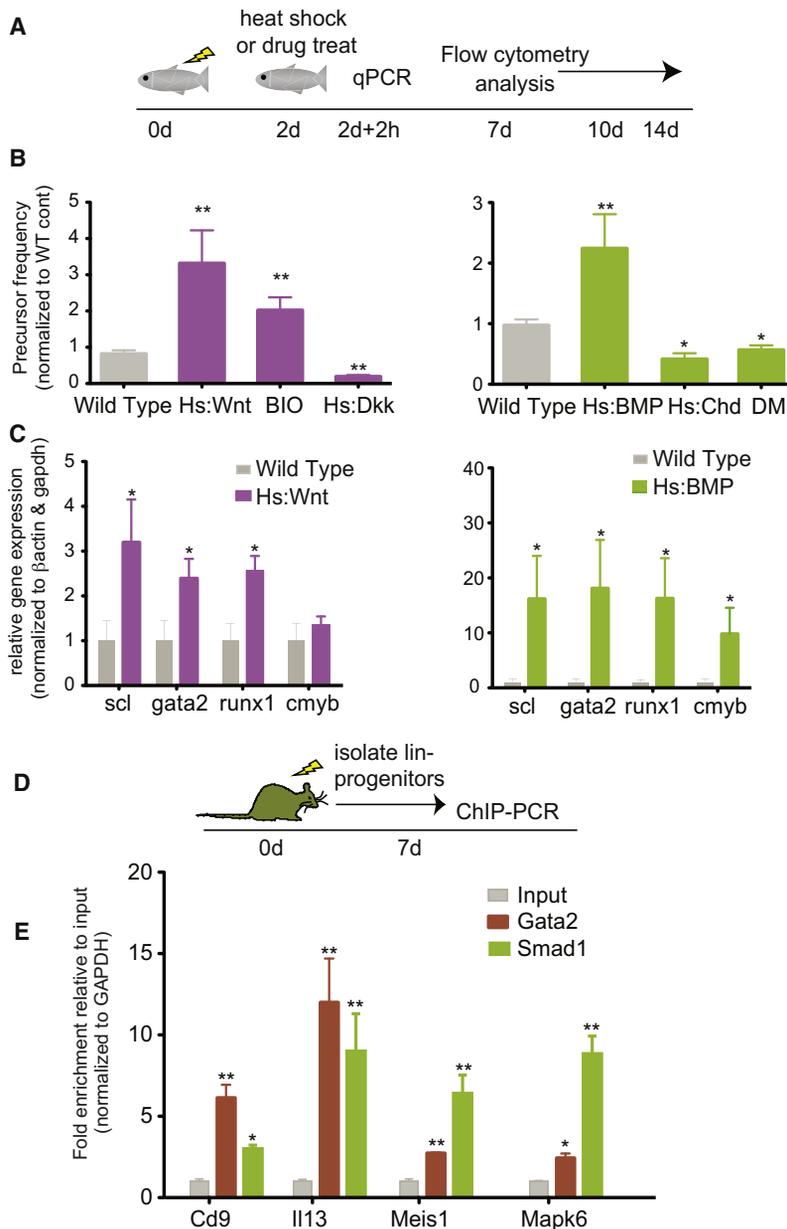

increase in the frequency of precursors (3- and 2-fold, respectively) during regeneration (Figure 1B) (Goessling et al., 2009). In contrast, inhibition of Wnt signaling by heat shock-induced expression of Dkk1 (Stoick-Cooper et al., 2007) led to diminished precursor levels (Figure 1B). Stimulation of the BMP pathway using a heat shock-inducible BMP2 ligand (Rentzsch et al., 2006) enhanced the number of precursors more than 2-fold (Figure 1B), whereas blocking the BMP pathway using either a heat shock-inducible Chordin (Tucker et al., 2008) or the BMP type I receptor chemical inhibitor dorsomorphin (DM) diminished precursor recovery levels to less than half of the wild-type levels (Figure 1B). Murine competitive bone marrow transplantation experiments were used to assess whether the roles for Wnt and BMP in hematopoietic regeneration were conserved and to determine whether the effects were cell-intrinsic (Figure S1A). We found that the *ex vivo* activation of Wnt signaling led to a greater number of animals with multilineage engraftment (Figure S1B). In contrast, *ex vivo* inhibition of BMP signaling abrogated engraftment (Figure S1B). These data suggest that Wnt and BMP have a conserved, cell-autonomous role during adult hematopoietic regeneration.

The transcriptional effects of BMP and Wnt signaling were evaluated by studying the expression of hematopoietic genes in zebrafish WKM after irradiation following a 2 hr heat shock induction of BMP2 or Wnt8. Activation of the pathways was confirmed using quantitative PCR (qPCR) for the BMP2 and Wnt8 ligands as well as known downstream targets such as *id1* for BMP and *cyclind1* for Wnt (Figure S1C). Overexpression of BMP increased the levels of the hematopoietic genes *scl*, *runx1*, *c-myb*, and *gata2*, whereas Wnt stimulation increased the expression of *scl*, *runx1*, and *gata2* (Figure 1C). These data demonstrate that during *in vivo* regeneration, BMP and Wnt pathways regulate hematopoietic targets at the level of gene expression, which led us to further investigate whether the signaling-directed transcription factors directly bind to enhancer elements of blood genes.

We next asked whether Smad1, which is a transcription factor activated by BMP signaling, co-occupied hematopoietic genes with the lineage regulator Gata2. In multilineage hematopoietic progenitors, Gata2 is an essential transcription factor that binds to the regulatory elements in genes expressed in progenitors and differentiated lineages (Tsai et al., 1994; Wilson et al., 2010). In order to obtain sufficient cell numbers to perform chromatin immunoprecipitation (ChIP) analysis, a mouse irradiation injury model was used (Hooper et al., 2009). Lineage-negative progenitors were isolated from mice 7 days after a sublethal irradiation, and then ChIP-PCR was performed for known targets of Gata2 (Figure 1D) (Wilson et al., 2010). Smad1 and Gata2 co-occupied hematopoietic genes including *Cd9*, *Il13*, *Meis1*, and *Mapk6* (Figure 1E). Together, these results indicate that BMP and Wnt are required for regeneration and act at least in part by modulating genes bound by the lineage regulator Gata2.

TCF7L2 and SMAD1 Transcription Factors Co-occupy Genomic Sites with GATA Factors in an Erythroid Environment

We next asked whether the transcription factors activated by Wnt and BMP signaling cobind with blood-specific lineage

regulators genome-wide by performing ChIP-seq for TCF7L2/TCF4 (Wnt pathway) and SMAD1 (BMP pathway) as well as GATA1 and GATA2. ChIP-seq was performed in K562 cells, which are erythroleukemia cells that express GATA1 and GATA2, essential transcription factors for erythroid and progenitor cells, respectively (Cantor, 2005; Tsai et al., 1994; Tsiftoglou et al., 2009). Cells were treated with BIO to activate the Wnt pathway or BMP4 to activate the BMP pathway. Both TCF7L2 and SMAD1 showed substantial overlap with GATA1 and GATA2 at individual genes and genome-wide (Figures 2A and 2B). To confirm the specificity of the analysis, TCF7L2 and SMAD1 binding at known targets was analyzed (Figure S2A), and we found that inhibition of BMP signaling resulted in considerable loss of SMAD1 binding across the genome (Figure S2B).

Figure 1. BMP and Wnt Pathways Regulate Hematopoietic Regeneration

(A) Schematic of an irradiation-induced hematopoietic regeneration model. Adult zebrafish are irradiated with 20 Gy γ -irradiation at day 0, treated on day 2, and then WKM cells are dissected and analyzed by flow cytometry or by qPCR.

(B) Activation of the Wnt and BMP pathways enhances regeneration in zebrafish. Graphs depicting the relative frequency \pm standard error of the mean (SEM) of precursors in WKM relative to wild-type controls following manipulations to the Wnt (left) and BMP (right) pathways. * $p < 0.05$ and ** $p < 0.005$; p values calculated using Student's t test comparing wild-type control treated siblings to treated group.

(C) Activation of the Wnt (left) and BMP (right) pathways leads to upregulation of key hematopoietic genes. qPCR graphs of relative gene expression \pm SEM in WKM cells from wild-type, Hs:Wnt, or Hs:BMP 2 days post-irradiation following a 2 hr heat shock induction of Wnt8a or BMP2b transgene expression, respectively. * $p < 0.05$; p values calculated using Student's t test comparing wild-type control treated siblings to treated group.

(D and E) Gata2 colocalizes with Smad1 on hematopoietic targets in murine progenitor cells during regeneration. (D) Schematic of irradiation model. ChIP for Smad1 and Gata2 was performed on lineage-negative progenitors isolated from mice 7 days after a 6.5 Gy irradiation. (E) qPCR of whole-cell extracts (input), Gata2, and Smad1 ChIP. The bars show relative enrichment \pm SEM compared to input control. * $p < 0.05$ and ** $p < 0.005$; p values calculated using Student's t test comparing ChIP DNA to input control.

See also Figure S1.

If the main targets for TCF7L2 and SMAD1 are the blood genes regulated by GATA factors, then we should see enrichment for red blood cell genes in their targets. Functional classification of the genes occupied by TCF7L2 or SMAD1 in K562 erythroleukemia cells revealed enrichment for genes highly associated with red blood cell development (Figures S2C–S2E). If TCF7L2 and SMAD1 bind to the same sites as GATA1 and GATA2, then there should be enrichment for GATA motifs in the sites

bound by TCF7L2 or SMAD1. As expected, the most prominent motif in regions bound by TCF7L2 and SMAD1 was the GATA motif (Figure S2F). Scanning for GATA, SMAD, and TCF motifs across the regions bound by SMAD1, TCF7L2, GATA1, or GATA2 demonstrated enrichment of all three motifs in the bound sites (Figure S2G). Furthermore, Wnt and BMP stimulation did not significantly affect the binding of GATA factors (Figure S3). If GATA factors direct the binding of signaling factors, then the expectation would be to find them interacting with the same genomic sites at the same time. ChIP for SMAD1 was performed followed by ChIP for GATA2, and PCR showed that SMAD1 and GATA2 simultaneously occupied key erythroid genes (Figure 2C). These results are consistent with co-occupancy of TCF7L2 and SMAD1 with GATA1 and GATA2 in K562 cells and demonstrate

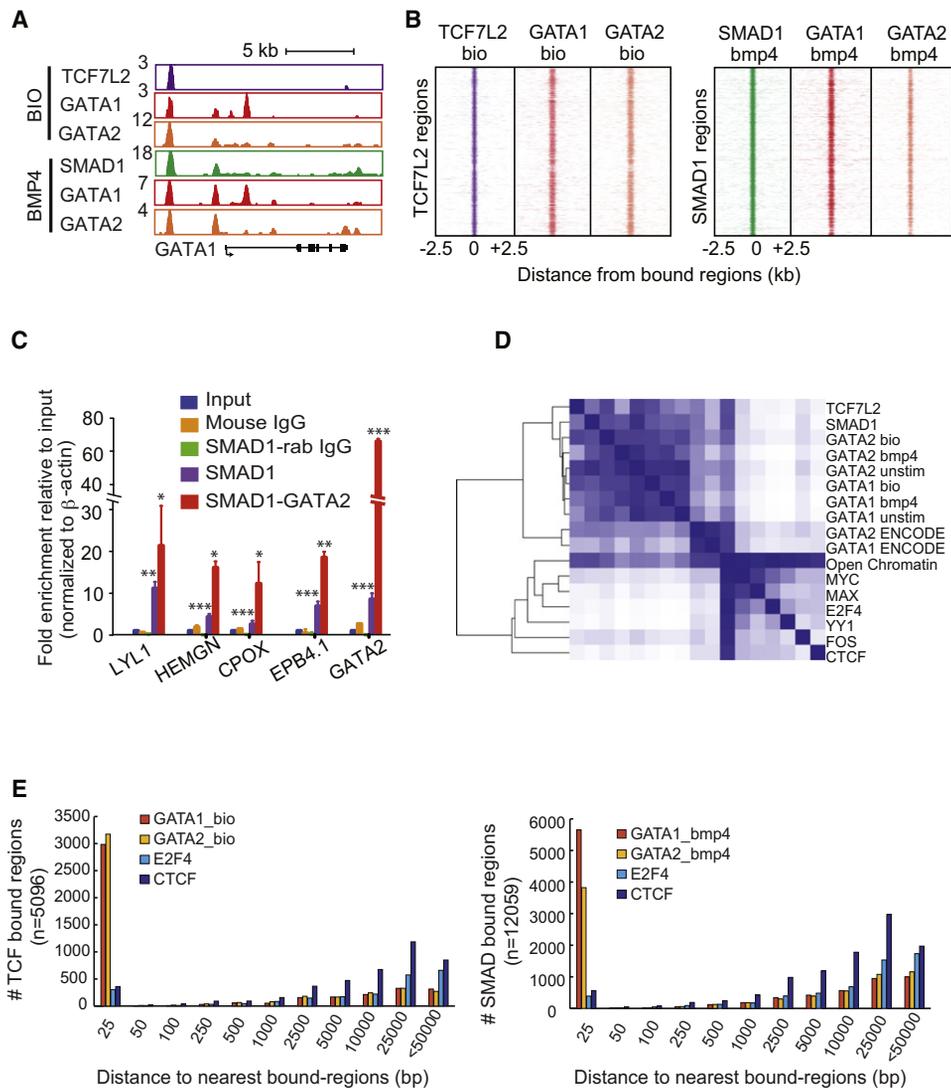

Figure 2. SMAD1 and TCF7L2 Co-occupy the Genome with Key Regulators of the Erythroid Lineage

(A) Gene track of the *GATA1* locus showing TCF7L2 (purple), GATA1 (red), GATA2 (orange), and SMAD1 (green) binding of specific genomic regions along the x axis and the total number of reads per million on the y axis.

(B) SMAD1 and TCF7L2 co-occupy genomic regions with GATA1 and GATA2. Region plots represent the distribution of GATA1- and GATA2-bound regions -2.5 to +2.5 kb relative to all TCF7L2- or SMAD1-bound regions in K562 cells.

(C) qPCR of whole-cell extracts (input), SMAD1 and control mouse IgG, sequential ChIP for GATA2, and control rabbit IgG on the SMAD1 ChIP. The bars show relative enrichment \pm SEM compared to input control. * $p < 0.08$ and ** $p < 0.04$, *** $p < 0.0005$; p values calculated using Student's t test comparing SMAD1 ChIP to input and SMAD1 ChIP to SMAD1-GATA2 sequential ChIP.

(D) Colocalization of SMAD1 and TCF7L2 is specific to lineage regulators. Heatmap depicting the relative level of colocalization of indicated factors, in K562 cells together with open chromatin data in this cell line.

(E) E2F4 and CTCF binding is not associated with TCF7L2 or SMAD1. The distance from the center of each TCF7L2 site (left) and SMAD1 site (right) to the center of the nearest site bound by the indicated transcription factor was determined. These distances were grouped into bins (x axis). The sum of bound sites in each bin is shown (y axis).

See also Figures S2 and S3.

that Wnt and BMP signaling were directed to genes occupied by GATA factors that specified the red blood cell state.

We next asked whether TCF7L2 or SMAD1 preferentially occupied the genome with GATA1 and GATA2 in K562 cells. Available data were analyzed for other transcription factors in K562 cells (Birney et al., 2007; Raney et al., 2011; Rosenbloom

et al., 2010). Both TCF7L2 and SMAD1 tend to bind sites with GATA1 and GATA2 but do not tend to occupy sites with the other tested transcription factors, despite previous reports that SMAD1 could interact with several of these factors in other tissue types (Chen et al., 2002; Kurisaki et al., 2003) (Figure 2D). In addition, the distance from TCF7L2 or SMAD1 sites to the nearest

binding sites for GATA1, GATA2, E2F4, and CTCF was calculated. The majority of TCF or SMAD sites were occupied by the GATA factors but were distant from E2F4 and CTCF sites (Figure 2E). These data indicate that the genome-wide co-occupancy of TCF7L2 and SMAD1 with GATA1 and GATA2 is specific.

Co-occupied Regions Encompass Enhancers

Analysis of TCF7L2 and SMAD1 localization with multiple transcription factors in K562 cells revealed that each of the transcription factors examined occupied “open” chromatin sites as defined by FAIRE-Seq and DNase-Seq, which measure DNA accessibility (Song et al., 2011), indicating that TCF7L2 and SMAD1 do not indiscriminately bind to all open and available DNA sites (Figure 2D). This led us to investigate the class of regulatory elements occupied by BMP and Wnt signaling factors.

Transcriptional regulatory elements fall into well-defined groups that can be defined by position relative to gene, chromatin modification state, and occupancy by known regulators. In order to identify the class of regulatory elements that Wnt and BMP factors co-occupy with master regulators, the enriched regions were mapped to positions relative to RefSeq genes. To assess differences in regions cobound by signaling and lineage regulators versus those bound by a lineage regulator alone, regulatory elements in regions bound by GATA factors and TCF7L2 or SMAD1 were examined and compared to those bound by GATA factors alone. The majority of regions for all groups mapped to introns and intergenic regions, similar to many enhancer elements (Heintzman and Ren, 2009), in contrast to E2F4, which occupies sites adjacent to promoter regions (Figure 3A). This pattern suggests that TCF7L2 and SMAD1 co-occupy distal regulatory elements with GATA1 and GATA2 master regulators.

Mammalian enhancers are associated with the histone modification H3K4me1 (Heintzman et al., 2007, 2009; Rada-Iglesias et al., 2011; Visel et al., 2009). Therefore we asked whether the distinct GATA regions showed differences in these modifications. Although each group was marked by H3K4me1 surrounding the GATA-bound regions, those sites where TCF7L2 or SMAD1 colocalize with GATA factors showed a greater enrichment (Figure 3B). To determine whether these enhancers tend to be associated with actively transcribed genes, the transcriptional activity of genes within 5 kilobases (kb) of the enriched regions was classified into distinct states of active, poised, and silent. Active genes were defined as the RefSeq genes marked by the histone modifications H3K4me3 and H3K36me3. A higher proportion of regions were enriched at active genes (51%–54%) compared to the proportion of all active genes (35%) (Figure S4). Thus, the co-occupied regions of TCF7L2, SMAD1, and GATA factors are predominantly occupying enhancers of actively transcribed genes. Together, these observations predict that the expression level of GATA target genes would be responsive to perturbation of Wnt and BMP signaling.

TCF7L2 and SMAD1 Enhance Transcriptional Activation Mediated by GATA2

TCF7L2 and SMAD1 co-occupy enhancers of active, cell-type-specific genes with GATA factors. To assess the consequences

of this co-occupancy on transcriptional output, we examined the effects of each transcription factor alone or in combination on the expression of the hematopoietic gene *LMO2*, which is bound by TCF7L2, SMAD1, GATA1, and GATA2 72 kb upstream of the transcriptional start site (TSS) in K562 cells (Figure 3C) (Landry et al., 2009). Induction of GATA2 alone was sufficient to increase reporter expression, whereas neither SMAD1 nor TCF7L2 alone had any effect (Figure 3D). In contrast, induction of either SMAD1 or TCF7L2 in the presence of GATA2 greatly enhanced reporter activity, indicating that the signaling factors affect transcription of blood-specific enhancer elements in combination with a lineage regulator (Figure 3D).

The observation that an increase in histone modifications is associated with active enhancers bound by TCF7L2, SMAD1, and GATA factors led to the hypothesis that binding of signaling factors could be influencing the chromatin state at these elements to affect transcriptional output. This could occur through recruitment of the histone acetyltransferase p300, with which both TCF/ β -catenin and SMAD are known to interact (Hecht and Stemmler, 2003; Nakashima et al., 1999; Pearson et al., 1999). If recruitment of p300 is dependent on the activity of the Wnt and BMP signaling pathways, then perturbations to either Wnt or BMP signaling should affect the localization of p300 to the enhancers of blood-specific genes. As determined by ChIP-PCR, activation of either the Wnt or the BMP pathway in K562 cells did result in an increase of p300 occupancy, whereas inhibition of the pathways diminished p300 occupancy at the enhancer elements of blood genes (Figure 3E). We conclude that TCF7L2 and SMAD1 cooperate with lineage regulators to enhance the transcription of their target genes through co-occupancy of enhancers that are activated through recruitment of p300.

TCF7L2 and SMAD1 Transcription Factors Co-occupy Genomic Sites with C/EBP α in a Myeloid Environment

We next investigated whether TCF7L2 and SMAD1 occupied the genome with a different master regulator in another hematopoietic lineage. ChIP-seq was performed for TCF7L2, SMAD1, and C/EBP α , a known master regulator of the myeloid lineage, in the U937 monocytic leukemia cell line. TCF7L2 and SMAD1 tend to occupy different sites in erythroid (K562) and myeloid (U937) lineages, with only 15% of sites in common (Figure 4A). Furthermore, the sites occupied by TCF7L2 and SMAD1 tend to be the sites occupied by C/EBP α in U937 cells and by GATA in K562 cells (Figures 4B and 4C). In the erythroid environment, TCF7L2, SMAD1, GATA1, and GATA2 were bound within erythroid genes such as *HEMGN*, but those sites were not bound by TCF7L2, SMAD1, or C/EBP α in the myeloid environment (Figures 4B, 4C, S5A, and S5B). Similarly, genes with a stronger association with myeloid cells such as *CXCR4* were bound by TCF7L2, SMAD1, and C/EBP α in the myeloid environments but were not bound by TCF7L2, SMAD1, GATA1, or GATA2 in the erythroid environment (Figures 4B, 4C, S5A, and S5B). Motif scanning of the sequences around TCF7L2-, SMAD1-, or GATA-bound sites in K562 showed enrichment for GATA, SMAD, and TCF motifs and absence of C/EBP motifs, whereas in the myeloid cells C/EBP motifs were present and GATA motifs absent (Figure S5C). Treatment of U937 cells with BIO or BMP4

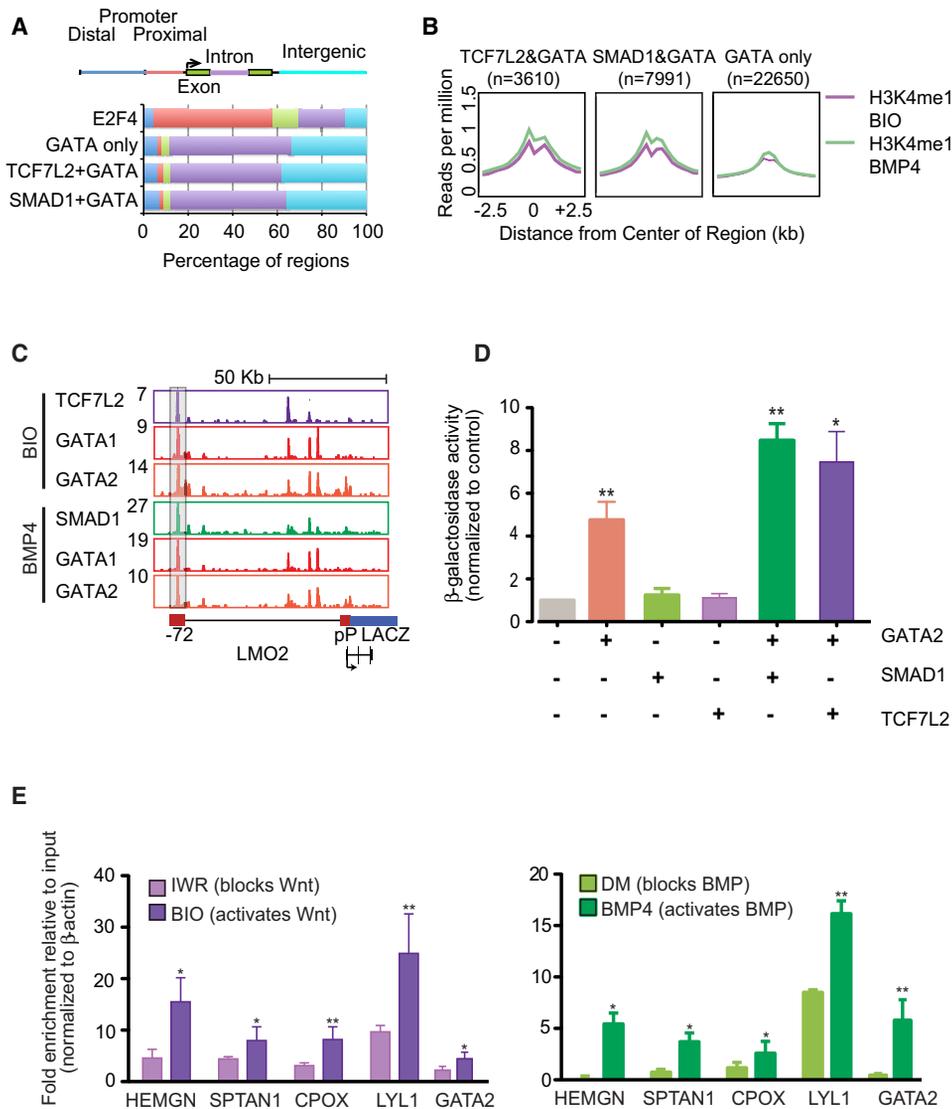

Figure 3. Signaling Factors Cooperate with Lineage Regulators at Distal Enhancers

(A) TCF7L2 and SMAD1 regions colocalize with GATA factors in intronic and intergenic regions. The groups of enriched regions occupied by GATA factors in K562 cells were divided into those occupied by GATA only, TCF7L2 and GATA, or SMAD1 and GATA. E2F4 is shown as a control. Each region was mapped to its closest RefSeq gene: distal promoter (blue), proximal promoter (red), exons (green), introns (purple), and intergenic regions (light blue). (B) TCF7L2 and SMAD1 regions that colocalize with GATA factors occupy mainly enhancer regions. Composite H3K4me1-BIO (purple) and H3K4me1-BMP4 (green) enrichment profile for TCF7L2 and GATA cobound regions, SMAD1 and GATA cobound regions, or regions occupied only by GATA in K562 cells. (C) Gene track of the *LMO2* locus. A schematic of the *LMO2* reporter indicating the enhancer and promoter regions included in the construct is shown below. (D) SMAD1 and TCF7L2 cooperate with GATA2 and enhance transcription of target genes. (E) Wnt and BMP signaling enhance p300 recruitment to blood-specific targets. ChIP-PCR graphs showing p300 occupancy after activation or inhibition of the Wnt (left) and the BMP (right) pathways. * $p < 0.06$, ** $p < 0.01$; p values calculated using Student's t test comparing inhibitor-treated samples to activator-treated samples. Values are mean \pm SEM. See also Figure S4.

had little influence on C/EBP α binding, showing that activation of the Wnt or BMP signaling pathways does not affect the genomic localization of the myeloid regulator (Figure S5D).

Analysis of bound regions among all the transcription factors analyzed showed a strong cell-type clustering (Figure 4D).

TCF7L2- and SMAD1-bound sites in K562 show a stronger correlation with GATA1- and GATA2-occupied regions than TCF7L2- and SMAD1-bound sites in U937. These data suggest that TCF7L2 and SMAD1 show cell-lineage-specific binding at sites co-occupied by master regulators.

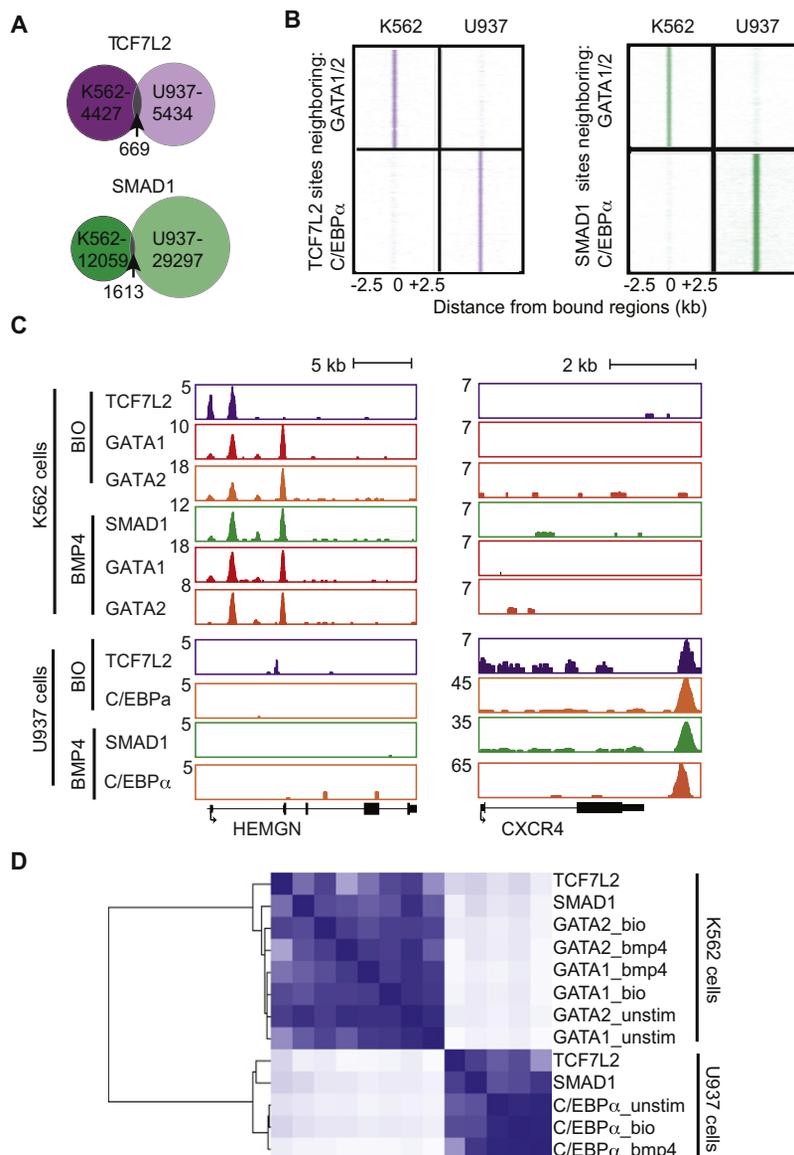

Figure 4. TCF7L2 and SMAD1 Co-occupy Genomic Regions with Cell-Type-Specific Lineage Regulators

C/EBP α -expressing K562 cells, while occupying new sites with C/EBP α exclusive of erythroid regulators (Figure 5C). An example of a newly occupied site lies near two genes, *ALAS2* and *APEX2*. *ALAS2* is expressed in erythroid cells (Sadlon et al., 1999), whereas *APEX2* is important in white blood cells (Ide et al., 2004). The binding of C/EBP α and SMAD1 at this position may result in repression of *ALAS2* in erythroid cells or activation of *APEX2* in white blood cells.

Gata1 Expression Redirects SMAD1 Binding during Differentiation

We next asked whether forced expression of an erythroid master regulator (Gata1) in an erythroblast progenitor cell line could restrict Smad1 binding to only erythroid targets during differentiation. To address this question, the estrogen-inducible Gata1 null erythroblast cell line (G1ER) was used, which was derived from targeted disruption of Gata1 in ESCs. Upon estradiol treatment, the Gata1 estrogen receptor fusion protein translocates into the nucleus and induces the red blood cell differentiation program (Figure 6A) (Cheng et al., 2009; Tsang et al., 1997; Yu et al., 2009). We identified the genome-wide binding of Gata2 and Smad1 in Gata1-deficient (G1E) and Gata1 and Smad1 in Gata1-induced (G1ER) cells following BMP4 stimulation. SMAD and GATA motifs were identified in all samples (Figure S6A). In G1E cells, Smad1 and Gata2 co-occupied genes of multiple hematopoietic lineages (Figures 6B, 6C, S6B, and S6C). During erythroid differentiation, Gata1 replaces Gata2 binding at erythroid genes (Bresnick et al., 2010; Grass et al., 2003). After Gata1 induction, Smad1 binding became more restricted to erythroid genes, and binding to genes expressed in the other lineages was diminished (Figures 6B, 6C, S6B, and S6C). Together the data reveal that induction of lineage-specific regulators alters Smad1 genomic occupancy.

C/EBP α Expression Redirects SMAD1 Binding in Erythroid Cells

If lineage-specific transcription factors direct the Wnt and BMP regulators to regulatory elements in distinct lineages, then expression of a master regulator of the myeloid lineage (e.g., C/EBP α) in an erythroid cell type should be capable of redirecting some of the signaling factors to novel sites occupied by the myeloid regulator. In order to test this hypothesis, an estrogen-inducible C/EBP α expressed in K562 cells was used (D'Alo' et al., 2003). Upon estradiol treatment, the C/EBP α estrogen receptor fusion protein translocates into the nucleus. SMAD1 and C/EBP α binding was determined by ChIP-seq in these cells following a 24 hr estradiol induction and a 2 hr BMP4 stimulation (Figure 5A). Expression of C/EBP α directed a fraction of SMAD1 to new sites occupied by C/EBP α (Figure 5B). SMAD1 was retained at GATA targets, such as *SLC6A9*, in

TCF7L2 and SMAD1 Co-occupancy with Master Regulators Occurs in Primary Hematopoietic Progenitors and Changes during Erythropoiesis

The shifts in SMAD1 occupancy following forced expression of C/EBP α or Gata1 in erythroid environments suggest that during regeneration and differentiation, when there are dynamic changes in the lineage regulators present, signaling factor occupancy will also change according to the cell state. To model a normal differentiation process, analogous to what occurs during regeneration, we examined TCF7L2 and SMAD1 genomic occupancy in primary human progenitor cells following in vitro expansion and differentiation. ChIP-seq was performed for GATA2, TCF7L2, and SMAD1 in mobilized peripheral blood CD34⁺ progenitor cells (Pro) (Figures 7A and S7A). GATA2 co-occupied more than 75% of TCF7L2- or SMAD1-enriched genes in these hematopoietic progenitor cells (Figures 7B, 7C, and S7B–S7D). In addition to a GATA motif, ETS and RUNX motifs were also enriched in GATA2-, SMAD-, and TCF-bound sequences (Figure S7E). This finding is consistent with recent genome-wide data from murine hematopoietic progenitors that indicate

that Gata2 co-occupies sites with multiple regulators, including Runx1 and ETS transcription factors Erg and Fli1, near genes important for multipotent stem cells (Wilson et al., 2010). Together with the binding data, these results imply that TCF7L2 and SMAD1 likely cobind with the entire progenitor transcriptional complex.

To determine how binding changes during differentiation, ChIP-seq for GATA1 and SMAD1 in erythroblast derived from CD34⁺ progenitors (CD34ery) was performed (Figures 7A and S7A). SMAD1 cobound with GATA1 in CD34-derived erythroblasts (Figures 7B and 7C). The genes bound by SMAD1 were fewer in the erythroid cells compared to the progenitor cells (2683 versus 8094). This change in SMAD1 occupancy suggested refinement of the binding sites from a multilineage to a fully differentiated state (Figures 7B and 7C). The bound genes were enriched for those that are characteristic of the differentiation stage (Figure S7D). In addition to the loss of many bound regions, further binding was acquired at erythroid genes (Figures 7B, 7C, and S7D). These data confirm that cobinding of BMP and Wnt regulators with lineage transcription factors occurs in primary hematopoietic cells in genes that regulate all hematopoietic lineages and shifts upon directed differentiation toward erythroid cells to erythroid-specific genes.

To ascertain whether genes bound by BMP and Wnt transcription factors were regulated by BMP and Wnt signaling, genome-wide expression analysis was performed on CD34⁺ cells with or without stimulation by BMP4 or BIO, respectively. The expression in unstimulated and stimulated cells was compared 2 hr after the shift to erythroid differentiation conditions. Differentially expressed genes in BMP4-treated groups compared to untreated controls were enriched for genes bound by SMAD1 (32%), and those differentially expressed in BIO-treated samples were enriched for those bound by TCF7L2 (31%) (Table S6). These data suggest that BMP and Wnt signaling coordinate with differentiation signals to alter gene expression via direct binding to common target genes with lineage master regulators.

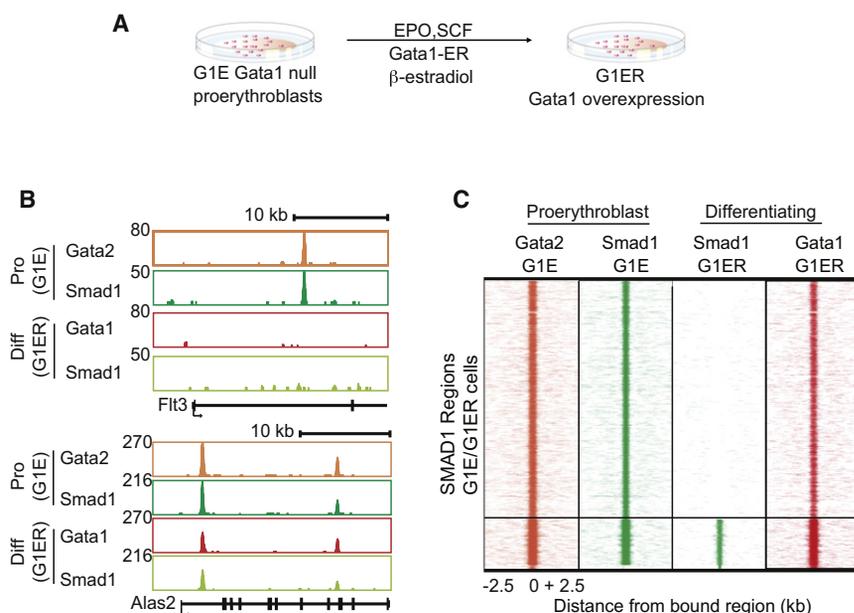

Figure 6. Smad1 Localization Is Directed by Gata1

(A) Schematic of the G1E, G1ER experiment. (B) Gene tracks of *Flt3* (top) and *Alas2* (bottom) showing differential binding of Gata2 and Smad1 in G1E Gata1 null cells (Proerythroblast) and Gata1 and Smad1 in G1ER erythroid cells (Differentiating). (C) Overexpression of Gata1 redefines the targets of Smad1. CHIP-seq region plots represent the distribution of regions bound by Smad1 and Gata2 in G1E and Gata1 and Smad1 in G1ER cells -2.5 and $+2.5$ kb relative to all Smad1-bound sites in G1E and G1ER combined. See also Figure S6.

In erythroid cells, SMAD1 is able to bind these same targets with GATA1, which helps activate these genes (Bresnick et al., 2010; Grass et al., 2003). Additionally, It has been suggested that GATA2 works in different complexes to target progenitor versus erythroid genes (Wilson

et al., 2010), and GATA2 is expressed at different levels in these two cell populations. We speculate that it is not only the function of an individual master regulator but also the combinations and the levels of each lineage regulator in a cell along with the transcriptional state of the target that help dictate the genomic location of signaling factors.

Here we provide a model for how this mechanism could be utilized to help orchestrate hematopoietic differentiation during a stress response. During hematopoietic regeneration when these pathways are required, the activation of BMP and Wnt signaling results in the colocalization of SMAD and TCF with the master regulators on genes defining progenitor cell fate. As regeneration continues and progenitor cells begin to differentiate, different master regulators activate the cell-specific genes of more mature hematopoietic lineages and again redefine the binding of signaling transcription factors. Colocalization of lineage and signaling factors has as a result the colocalization of signaling factors themselves. This fact may explain some of the synergistic effects observed between many signaling pathways (Schier and Talbot, 2005). As the BMP and Wnt pathways appear to have a selective function during regeneration, throughout this stress response, coupling transcriptional regulation to the transcription factors expressed highly in a cell lineage explains how BMP and Wnt signaling pathways can have cell-context-dependent effects.

Regeneration is a process of tissue self-renewal. Our data imply that an underlying mechanism of self-renewal is the control of the entire hematopoietic program through the collaboration of master and signaling transcription factors, which is similar to the mechanism by which core self-renewal factors in ESCs perform key roles in ESC fate. Our observation that the BMP and Wnt signaling transcription factors are associated with master regulators of multiple hematopoietic cell types provides insight into the effects of BMP and Wnt signaling that occur during development, regeneration, and disease.

DISCUSSION

Here we provide evidence that BMP and Wnt pathways play a dynamic role in hematopoietic regeneration through co-occupancy of regulatory elements with lineage regulators at cell-type-specific genes for each lineage. The co-occupancy of Smad1 and Gata2 was observed on blood targets in hematopoietic progenitors during in vivo regeneration. Lineage-restricted co-occupancy of TCF7L2 or SMAD1 with GATA1 and GATA2 in erythroid cells, C/EBP α in myeloid cells, and GATA2 in progenitors occurs genome-wide. This binding is selective for cell-specific enhancers bound by master regulators. BMP and Wnt signaling cooperate with lineage regulators to enhance transcription of cell-type-specific target genes. Lastly, ectopic expression of a lineage transcription factor was sufficient to direct the genomic localization of signaling-specific factors.

Master regulators direct the site selection of signaling transcription factors in every step during the differentiation process. Recent genome-wide studies have shown that signaling pathway transcription factors localize in binding sites adjacent to ESC master regulators (Chen et al., 2008; Cole et al., 2008; Young, 2011). Our data along with those of Mullen et al. show that this mechanism occurs in many cell types and establishes an order by which the lineage regulators recruit the signaling factors to sites of active genes of biological relevance throughout the whole genome (Mullen et al., 2011). Alterations of the expression and binding of hematopoietic lineage regulators to target genes during regeneration or differentiation can dictate the binding of signaling factors.

Signaling factors selectively colocalize with master regulators, but our studies hint that other factors may help fine-tune signaling factor binding. For example, the transcriptional status of a gene can modify SMAD1 binding. In CD34 $^+$ progenitor cells, SMAD1 cobinds with GATA2 on genes expressed in progenitors but is mostly absent from erythroid genes that are not expressed.

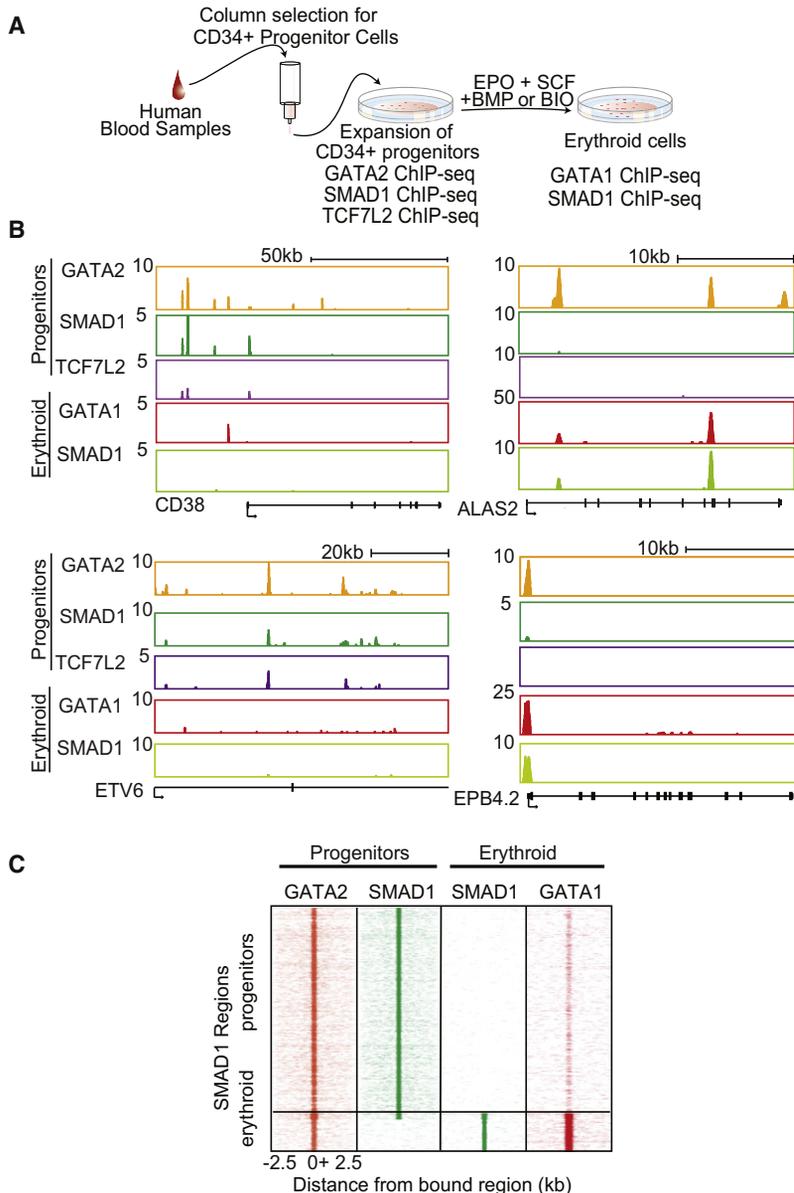

Figure 7. Binding of Signaling Factors Changes during Differentiation

(A) Schematic of CD34⁺ experiment.

(B) Gene tracks of *CD38*, *ETV6*, *ALAS2*, and *EPB4.2* showing differential binding of GATA2, SMAD1, and TCF7L2 in undifferentiated CD34⁺ progenitors and GATA1 and SMAD1 in differentiated erythroblasts.

(C) SMAD1 binding becomes restricted to mainly erythroid genes after differentiation of CD34⁺ hematopoietic cells toward erythrocytes. ChIP-seq region plots represent the distribution of SMAD1-occupied regions in CD34⁺ progenitors (pro) and in vitro differentiated erythroblasts (ery). GATA2 and SMAD1 in CD34⁺ progenitors and SMAD1 and GATA1 in erythroid differentiated CD34⁺ cells -2.5 to $+2.5$ kb relative to all SMAD1-bound regions in CD34⁺ progenitors and differentiated erythroblasts are shown. See also Figure S7.

Chromatin Immunoprecipitation

ChIP experiments were performed as previously described (Lee et al., 2006) with slight modifications, which are described in [Extended Experimental Procedures](#). A summary of the bound regions and bound genes determined for all ChIP-seq data is contained within [Tables S3, S4, and S5](#). For ChIP-seq experiments, the following antibodies were used: Smad1 (Santa Cruz sc7965), TCF7L2 (TCF4 Santa Cruz sc8631), C/EBP α (Santa Cruz sc9314), Gata1 (Santa Cruz sc265), Gata2 (Santa Cruz sc9314), p300 (Santa Cruz sc585), and H3K4me1 (Abcam ab8895). Samples were prepared for sequencing using Illumina Genomic DNA kit or TruSeq according to the manufacturer instructions. Also see [Extended Experimental Procedures](#) for details on ChIP and ChIP-seq sample preparation and analysis.

ChIP-PCR Analysis of Lineage-Negative Bone Marrow Cells

ChIP in lineage-negative cells isolated from mouse bone marrow was performed as described above. Primers were designed for known Gata2 targets. qPCR reactions were done with iQ SYBR-GREEN Supermix (BIORAD 170-8880), and a CFX-384 Real-Time PCR Detection System (BIORAD) thermal cycler was used. Expression of each gene was normalized to *Gapdh*, and relative levels were calculated using the $\Delta\Delta C_t$ method (Applied Bio-

systems). Quantities are expressed as fold change compared to input controls. Primers are listed in [Table S2](#).

Sequential Chromatin Immunoprecipitation

ChIP analysis was performed, and immunoprecipitated DNA fragments were eluted from the beads by addition of 55 μ l 10 mM DTT and incubated at 37°C for 30 min. The supernatant was transferred to a new tube and the material was diluted 30 \times with sonication buffer and served as the starting material for the second ChIP. ChIP-PCR was performed as described above. See also [Extended Experimental Procedures](#).

Motif Counting

The genomic sequence ± 2.5 kb from the center of each enriched region in the dataset indicated was downloaded from the UCSC website with repeats masked with "N." A window of 250 bp was shifted across each sequence at 50 bp intervals, and the number of occurrences of the complete motif sequence or its reverse complement within the window was counted. An

EXPERIMENTAL PROCEDURES

Zebrafish Irradiation-Induced Regeneration

Zebrafish were maintained as described (Westerfield, 2000). Irradiation-induced regeneration assays were performed as previously described (Burns et al., 2005; Traver et al., 2004). For heat shock treatments, small fish tanks were placed at 37°C for 16 hr. For small-molecule treatments, fish were soaked for 16 hr in fish water containing drug dissolved in DMSO, 2 μ M BIO, or 10 μ M DM. On days 2, 7, and 14 post-irradiation, WKM cells were analyzed on an LSRII for FSC/SSC parameters. See also [Extended Experimental Procedures](#).

Cell Line Culture Conditions and Stimulation

K562 and U937 cells were maintained in IMDM and RPMI media, respectively, supplemented with fetal calf serum, glutamine, and penicillin/streptomycin. Culture conditions for CEBP α -K562, G1E, G1ER, and human hematopoietic CD34⁺ cells as well as differentiation media and stimulation conditions are described in [Extended Experimental Procedures](#).

averaged motif occurrence in each scanning window was plotted across the ± 2.5 kb regions.

Heatmap Analysis of ChIP-Seq Occupancy

ChIP-seq enrichment for the indicated factor or modification was determined in 100 bp bins (enrichment in the bin as counts per million) centered on the enriched region of a given ChIP-seq dataset. Java Treeview (<http://www.jtreeview.sourceforge.net>) was used to visualize the data and generate figures shown in this manuscript.

Distance from TCF7L2- or SMAD1-Enriched Regions to Nearest Transcription Factor-Bound Region

The distance (in bp) from each TCF7L2 or SMAD1 site in K562 cells to the nearest site of each transcription factor was calculated. The distance from the boundary of each TCF7L2- or SMAD1-enriched region to the boundary of the nearest site bound by the indicated transcription factor was determined. These distances were grouped into bins (x axis), with the x axis value indicating the upper limit of each bin. The sum of regions in each bin is shown (y axis).

Assignment to Regulatory Regions in K562 Cells

Each enriched region was uniquely assigned into a category of exon, intron, proximal promoter (from 1 kb upstream to the TSS), distal promoter (from 10 kb upstream to 1 kb upstream of the TSS), and intergenic region (more than 10 kb upstream away from body of the gene) according to MySQL access to the UCSC hg18 RefSeq table. When an enriched region could be mapped to more than one regulatory region category because of overlapping genes, it was classified into a regulatory region class in preferential order of exon, intron, proximal promoter, distal promoter, and intergenic region.

Genome-wide Expression Analysis

Affymetrix U133plus2.0 microarrays were used to assess gene expression changes in CD34⁺ cells with or without Wnt or BMP pathway stimulation. Arrays were done on control, 0.5 μ M BIO-treated, or 25 ng/ml rhBMP4-treated cells 2 hr after a shift to erythroid differentiation media. See also [Extended Experimental Procedures](#).

Reporter Assays

K562 cells were transfected using AMAXA nucleofactor according to the manufacturer instructions. β -galactosidase activity was measured with the Galacto-Star kit (Applied Biosystems). See also [Extended Experimental Procedures](#).

ACCESSION NUMBERS

Microarray (GSE26351) and ChIP-seq (Superseries—GSE29196, datasets—GSE29193, GSE29194, GSE29195) data were deposited in GEO (<http://www.ncbi.nlm.nih.gov/geo/>) under the accession numbers indicated.

SUPPLEMENTAL INFORMATION

Supplemental Information includes Extended Experimental Procedures, seven figures, and six tables and can be found with this article online at <doi:10.1016/j.cell.2011.09.044>.

ACKNOWLEDGMENTS

We would like to acknowledge A. Mullen and D. Orlando for helpful discussions and sharing critical insights prior to publication and G. Frampton for analytical advice and development of the ChIP-seq analysis platform. We thank F. Rentzsch and M. Hammerschmidt for the Hs:BMP zebrafish line, J. Tucker and M. Mullins for the Hs:Chordin zebrafish line, and T. Schlaeger for the GATA2 expression plasmid. We are grateful to X. Bai and R. White for critical reviews of the manuscript and O. Tamplin for computational advice. The Whitehead Genome Technology Core was instrumental in timely data production and analysis support, especially S. Gupta. Microarray studies were performed by the Molecular Genetics Core Facility at Children's Hospital Boston,

supported by NIH-P50-NS40828 and NIH-P30-HD18655. This work was supported by NIH #5PO1HL32262-29 and #5R01HL048801-18 (to L.I.Z.), NIH 1R01DK080040-01 (to R.F.P.), R01-HG002668 (to R.A.Y.), NIH K01 DK085270-02 (to T.V.B.), NIH U01 HL100001, NIH 1 RC2HL102815, and ROFAR (to G.Q.D.), NIH T32HL007623 (to G.C.H.), HHMI (to L.I.Z. and G.Q.D.), and EMBO fellowship and Jane Coffin Childs Memorial Fund (to E.T.). L.I.Z. is a founder and stock holder of Fate, Inc. and a scientific advisor for Stemgent. G.Q.D. is a member of the Scientific Advisory Boards of MPM Capital, Inc., Epizyme, Inc., and iPierian, Inc.
