In this paper, we generalize existing frameworks for  $\mathcal{H}_2 \otimes \mathcal{L}_2$ -optimal model order reduction to a broad class of parametric linear time-invariant systems. To this end, we derive first-order necessary optimality conditions for a class of structured reduced-order models, and then building on those, propose a stability-preserving optimization-based method for computing locally  $\mathcal{H}_2 \otimes \mathcal{L}_2$ -optimal reduced-order models. We also make a theoretical comparison to existing approaches in the literature, and in numerical experiments, show how our new method, with reasonable computational effort, produces stable optimized reduced-order models with significantly lower approximation errors.

## 1 Introduction

Given parameters  $p = (p_1, ..., p_d) \in \mathcal{P} \subset \mathbb{R}^d$ , we consider parametric linear time-invariant systems with time-domain state-space realizations

$$E(\mathsf{p})\dot{x}(t;\mathsf{p}) = A(\mathsf{p})x(t;\mathsf{p}) + B(\mathsf{p})u(t), \quad x(0;\mathsf{p}) = 0,$$
  
$$y(t;\mathsf{p}) = C(\mathsf{p})x(t;\mathsf{p}),$$
 (1)

where  $t \geq 0$  is the time and H is the associated (parameterized) transfer function in the Laplace domain, i.e.,  $H(s; \mathbf{p}) = C(\mathbf{p})(sE(\mathbf{p}) - A(\mathbf{p}))^{-1}B(\mathbf{p}) \in \mathbb{C}^{p \times m}$  with  $s \in \mathbb{C}$  being the Laplace variable. Matrices  $E(\mathbf{p}), A(\mathbf{p}) \in \mathbb{R}^{n \times n}$  describe the system dynamics, while  $B(\mathbf{p}) \in \mathbb{R}^{n \times m}$  is the input matrix,  $C(\mathbf{p}) \in \mathbb{R}^{p \times n}$  the output matrix,  $x(t; \mathbf{p}) \in \mathbb{R}^n$  the state,  $u(t) \in \mathbb{R}^m$  the input, and  $y(t; \mathbf{p}) \in \mathbb{R}^p$  the output. For all parameter values  $\mathbf{p} \in \mathcal{P}$ , we assume that  $E(\mathbf{p})$  is invertible and system (1) is asymptotically stable, i.e., the set of eigenvalues of the matrix pencil  $\lambda E(\mathbf{p}) - A(\mathbf{p})$ , which we denote as  $\Lambda(A(\mathbf{p}), E(\mathbf{p}))$ , is in the open left half of the complex plane. Defining

$$\alpha(A(\mathsf{p}), E(\mathsf{p})) := \max\{\operatorname{Re}(\lambda) : \lambda \in \Lambda(A(\mathsf{p}), E(\mathsf{p}))\},\$$

i.e., the spectral abscissa of matrix pencil  $\lambda E(\mathbf{p}) - A(\mathbf{p})$ , the stability assumption can equivalently be written as  $\max_{\mathbf{p} \in \mathcal{P}} \alpha(A(\mathbf{p}), E(\mathbf{p})) < 0$ .

Such parametric systems arise in applications where the parameters are used to describe things like geometric or physical properties. In practice, for fidelity, the state-space dimension n is typically large, and so corresponding numerical calculations can be prohibitively expensive, even in the non-parametric case. One approach to dealing with this is parametric model order reduction (MOR), i.e., constructing a parametric reduced-order model (ROM)

$$\widehat{E}(\mathbf{p})\widehat{x}(t;\mathbf{p}) = \widehat{A}(\mathbf{p})\widehat{x}(t;\mathbf{p}) + \widehat{B}(\mathbf{p})u(t), \quad \widehat{x}(0;\mathbf{p}) = 0, 
\widehat{y}(t;\mathbf{p}) = \widehat{C}(\mathbf{p})\widehat{x}(t;\mathbf{p}),$$
(2)

that has similar dynamical behavior to the full-order model (FOM) (1) across the entire parameter domain  $\mathcal{P}$  but with a much smaller dimension  $r \ll n$  and matrix-valued functions  $\widehat{E}, \widehat{A}, \widehat{B}, \widehat{C}$  that are cheap to evaluate. For (2),  $\widehat{E}(\mathsf{p}), \widehat{A}(\mathsf{p}) \in \mathbb{R}^{r \times r}, \widehat{B}(\mathsf{p}) \in \mathbb{R}^{r \times m}$  and  $\widehat{C}(\mathsf{p}) \in \mathbb{R}^{p \times r}$ , and its associated transfer function  $\widehat{H}$  is such that  $\widehat{H}(s;\mathsf{p}) = \widehat{C}(\mathsf{p})(s\widehat{E}(\mathsf{p}) - \widehat{A}(\mathsf{p}))^{-1}\widehat{B}(\mathsf{p}) \in \mathbb{C}^{p \times m}$ . Therefore, such a ROM can be simulated faster over the entire parameter domain  $\mathcal{P}$ . As a shorthand, we denote systems (1) and (2) by  $\Sigma_{\mathcal{P}} \coloneqq (E, A, B, C)$  and  $\widehat{\Sigma}_{\mathcal{P}} \coloneqq (\widehat{E}, \widehat{A}, \widehat{B}, \widehat{C})$ , respectively.

In the simpler setting of non-parametric  $\mathcal{H}_2$ -optimal MOR, a ROM's quality is measured via the Hardy  $\mathcal{H}_2$  norm in the s variable, i.e., the average discrepancy in the frequency domain between the FOM and ROM is measured. The two most well-known algorithms for  $\mathcal{H}_2$ -optimal MOR are the iterative rational Krylov algorithm (IRKA) [14] and the two-sided iteration algorithm (TSIA) [29]. Respectively, they are based on the interpolatory first-order necessary conditions (FONC) from Meier and Luenberger [18] and Gramian-based FONC from Wilson [28], which are respectively called the Meier-Luenberger and Wilson conditions; for more details, see [6, 14, 27, 29].

For parametric model order reduction, many approaches have been developed over the years; see [4,5] for comprehensive surveys. Our specific focus here is  $\mathcal{H}_2 \otimes \mathcal{L}_2$ -optimal parametric MOR, which was originally proposed by Baur et al. [3]. This mixed-norm approach additionally averages the error in the p variable, i.e., in the parameter domain. However, in [3], this was done under very special assumptions, which include requiring that  $E, A, \widehat{E}, \widehat{A}$  are all constant functions of the parameter. Another  $\mathcal{H}_2 \otimes \mathcal{L}_2$ -optimal framework was proposed in [13, Chapter 3], where Grimm modified the  $\mathcal{H}_2 \otimes \mathcal{L}_2$  norm considered in [3] so that FOMs such as (1) are considered, but all matrix-valued functions are assumed to be analytic and  $\widehat{E}$  and  $\widehat{A}$  remain non-parametric. Meanwhile, in [22, Chapter 4], Petersson considered a discretized  $\mathcal{H}_2 \otimes \mathcal{L}_2$ -norm optimization problem. Here, we extend the approach of Baur et al. [3] to general parametric systems, in particular, where all coefficients can actually vary with the parameter.

In Section 2, we review both standard non-parametric  $\mathcal{H}_2$ -optimal MOR and parametric  $\mathcal{H}_2 \otimes \mathcal{L}_2$ -optimal MOR, and then give various definitions and results that we will need here. Our main theoretical result, the derivation of the gradient and Wilson-type FONC for our generalized  $\mathcal{H}_2 \otimes \mathcal{L}_2$ -optimal framework, is given in Section 3. In Section 4, we show how our new results differ with respect to the earlier results of [3, 13, 22], while in Section 5 we discuss a TSIA-like algorithm for parametric MOR and its limitations. In Section 6, we leverage our newly derived FONC from Section 3 to propose a new optimization-based algorithm for computing locally-optimal ROMs for  $\mathcal{H}_2 \otimes \mathcal{L}_2$ -optimal parametric MOR. Finally, we validate our new algorithm on some examples in Section 7 and make concluding remarks in Section 8.

## 2 Preliminaries

We begin with the prerequisite background.

## 2.1 Non-parametric $\mathcal{H}_2$ -optimal MOR

Consider the non-parametric system

$$E\dot{x}(t) = Ax(t) + Bu(t), \quad x(0) = 0,$$
  
 $y(t) = Cx(t),$  (3)

with the same dimensions as (1). We refer to (3) as a (non-parametric) FOM of order n, and we assume that E is invertible and (3) is asymptotically stable. Furthermore, let

$$\widehat{E}\dot{\widehat{x}}(t) = \widehat{A}\widehat{x}(t) + \widehat{B}u(t), \quad \widehat{x}(0) = 0,$$

$$\widehat{y}(t) = \widehat{C}\widehat{x}(t),$$
(4)

be a non-parametric analogue of (2), with the same dimensions, i.e., a ROM of order r. We respectively use  $\Sigma$  and  $\widehat{\Sigma}$  to denote (3) and (4). For the state-space representation of the error system, with transfer function  $H - \widehat{H}$ , we use

$$\underbrace{\begin{bmatrix} E & 0 \\ 0 & \widehat{E} \end{bmatrix}}_{=:E_{e}} \underbrace{\begin{bmatrix} \dot{x}(t) \\ \dot{\hat{x}}(t) \end{bmatrix}}_{=:A_{e}} = \underbrace{\begin{bmatrix} A & 0 \\ 0 & \widehat{A} \end{bmatrix}}_{=:A_{e}} \underbrace{\begin{bmatrix} x(t) \\ \hat{x}(t) \end{bmatrix}}_{=:B_{e}} + \underbrace{\begin{bmatrix} B \\ \widehat{B} \end{bmatrix}}_{=:B_{e}} u(t),$$

$$y(t) - \widehat{y}(t) = \underbrace{\begin{bmatrix} C & -\widehat{C} \end{bmatrix}}_{=:C_{e}} \underbrace{\begin{bmatrix} x(t) \\ \hat{x}(t) \end{bmatrix}}_{=:C_{e}},$$
(5)

where  $E_e, A_e \in \mathbb{R}^{(n+r)\times(n+r)}, B_e \in \mathbb{R}^{(n+r)\times m}$ , and  $C_e \in \mathbb{R}^{p\times(n+r)}$ .

Following [1, Chapter 5], we begin with the Hardy  $\mathcal{H}_2$  norm. Given a function  $G: \mathbb{C} \to \mathbb{C}^{p \times m}$  that is analytic in the open right half-plane, the  $\mathcal{H}_2$  norm of G is

$$\|G\|_{\mathcal{H}_2} := \left(\frac{1}{2\pi} \int_{-\infty}^{\infty} \|G(\mathbf{i}\omega)\|_{\mathrm{F}}^2 d\omega\right)^{1/2},$$

where  $\omega \in \mathbb{R}$  is the (angular) frequency and  $\|\cdot\|_F$  denotes the Frobenius norm. For a linear time-invariant system, its  $\mathcal{H}_2$  norm is the  $\mathcal{H}_2$  norm of its transfer function. Note that by our invertibility and stability assumptions, the  $\mathcal{H}_2$  norm of  $\Sigma$  is finite.

Even though the  $\mathcal{H}_2$  system norm is defined in the frequency domain, the time-domain Lebesgue  $\mathcal{L}_{\infty}$  norm of the output error is bounded in terms of the  $\mathcal{H}_2$  norm of error system (5) and the  $\mathcal{L}_2$  norm of the input u, i.e.,

$$||y - \widehat{y}||_{\mathcal{L}_{\infty}} \le ||H - \widehat{H}||_{\mathcal{H}_2} ||u||_{\mathcal{L}_2}.$$

$$(6)$$

Thus, if we desire to find a ROM that minimizes the  $\mathcal{L}_{\infty}$  norm of the output error, (6) motivates finding the  $\mathcal{H}_2$ -optimal ROM, i.e., the one that most reduces  $||H - \hat{H}||_{\mathcal{H}_2}$ . Again due to our assumptions, note that  $||H - \hat{H}||_{\mathcal{H}_2}$  is finite.

In [28], the starting point for deriving the Wilson conditions is rewriting the squared  $\mathcal{H}_2$  norm of  $H - \widehat{H}$  as

$$\left\| H - \widehat{H} \right\|_{\mathcal{H}_2}^2 = \operatorname{tr} \left( C_e P_e C_e^{\mathsf{T}} \right) = \operatorname{tr} \left( B_e^{\mathsf{T}} Q_e B_e \right), \tag{7}$$

where  $P_e = P_e^{\mathsf{T}}$  and  $Q_e = Q_e^{\mathsf{T}}$ , both in  $\mathbb{R}^{(n+r)\times(n+r)}$ , define the controllability and observability Gramians  $P_e$  and  $E_e^{\mathsf{T}}Q_eE_e$ , respectively, of the error system (5), and so

$$0 = A_e P_e E_e^{\mathsf{T}} + E_e P_e A_e^{\mathsf{T}} + B_e B_e^{\mathsf{T}}, 0 = A_e^{\mathsf{T}} Q_e E_e + E_e^{\mathsf{T}} Q_e A_e + C_e^{\mathsf{T}} C_e.$$

Based on (7), the FONC for  $\mathcal{H}_2$ -optimality are

$$0 = \widehat{Q}^{\mathsf{T}} \widehat{A} \widehat{P} + \widetilde{Q}^{\mathsf{T}} A \widetilde{P},$$

$$0 = \widehat{Q}^{\mathsf{T}} \widehat{E} \widehat{P} + \widetilde{Q}^{\mathsf{T}} E \widetilde{P},$$

$$0 = \widehat{Q}^{\mathsf{T}} \widehat{B} + \widetilde{Q}^{\mathsf{T}} B,$$

$$0 = \widehat{C} \widehat{P} - C \widetilde{P}.$$
(8)

where  $P = P^{\mathsf{T}} \in \mathbb{R}^{n \times n}$ ,  $\widehat{P} = \widehat{P}^{\mathsf{T}} \in \mathbb{R}^{r \times r}$ , and  $\widetilde{P} \in \mathbb{R}^{n \times r}$  are obtained from the block partitioning of the matrix  $P_e = \begin{bmatrix} P & \widetilde{P} \\ \widetilde{P}^{\mathsf{T}} & \widehat{P} \end{bmatrix}$ , while  $Q = Q^{\mathsf{T}} \in \mathbb{R}^{n \times n}$ ,  $\widehat{Q} = \widehat{Q}^{\mathsf{T}} \in \mathbb{R}^{r \times r}$ , and  $\widetilde{Q} \in \mathbb{R}^{n \times r}$  are obtained from the corresponding partitioning in  $Q_e = \begin{bmatrix} Q & \widetilde{Q} \\ \widetilde{Q}^{\mathsf{T}} & \widehat{Q} \end{bmatrix}$ .

**Remark 2.1.** Actually, in [28], Wilson derived (8) for the special case where  $E = I_n$ , the  $n \times n$  identity. In [27], it is also assumed that  $E = I_n$ , where (8) is given in [27, Theorem 3.3]. As part of our derivation of new FONC for parametric systems, in Section 3 we explain how (8) holds for arbitrary invertible matrices E.

## 2.2 Parametric $\mathcal{H}_2 \otimes \mathcal{L}_2$ -optimal MOR

Now consider the parametric systems  $\Sigma_{\mathcal{P}}$  and  $\widehat{\Sigma}_{\mathcal{P}}$ , with their associated error system  $H - \widehat{H}$ :

$$\underbrace{\begin{bmatrix} E(\mathsf{p}) & 0 \\ 0 & \widehat{E}(\mathsf{p}) \end{bmatrix}}_{=:E_{e}(\mathsf{p})} \underbrace{\begin{bmatrix} \dot{x}(t;\mathsf{p}) \\ \widehat{x}(t;\mathsf{p}) \end{bmatrix}}_{=:E_{e}(\mathsf{p})} = \underbrace{\begin{bmatrix} A(\mathsf{p}) & 0 \\ 0 & \widehat{A}(\mathsf{p}) \end{bmatrix}}_{=:A_{e}(\mathsf{p})} \underbrace{\begin{bmatrix} x(t;\mathsf{p}) \\ \widehat{x}(t;\mathsf{p}) \end{bmatrix}}_{=:B_{e}(\mathsf{p})} + \underbrace{\begin{bmatrix} B(\mathsf{p}) \\ \widehat{B}(\mathsf{p}) \end{bmatrix}}_{=:B_{e}(\mathsf{p})} u(t),$$

$$y(t;\mathsf{p}) - \widehat{y}(t;\mathsf{p}) = \underbrace{\begin{bmatrix} C(\mathsf{p}) & -\widehat{C}(\mathsf{p}) \end{bmatrix}}_{=:C_{e}(\mathsf{p})} \underbrace{\begin{bmatrix} x(t;\mathsf{p}) \\ \widehat{x}(t;\mathsf{p}) \end{bmatrix}}_{=:C_{e}(\mathsf{p})},$$
(9)

where  $E_e(\mathbf{p}), A_e(\mathbf{p}) \in \mathbb{R}^{(n+r)\times(n+r)}, B_e(\mathbf{p}) \in \mathbb{R}^{(n+r)\times m}$ , and  $C_e(\mathbf{p}) \in \mathbb{R}^{p\times(n+r)}$ . For this parametric MOR setting, we use the following assumptions.

**Assumption 2.2** (Assumptions on the FOM). We assume:

- (a)  $\mathcal{P}$  is a non-degenerate d-dimensional box aligned with the axes,
- (b) E(p) is invertible for all  $p \in \mathcal{P}$ ,
- (c) the system  $\Sigma_{\mathcal{P}}$  is asymptotically stable for all  $p \in \mathcal{P}$ ,
- (d) the functions E, A, B, C are continuous over  $\mathcal{P}$ .

Following [3], we now define parametric analogues of the  $\mathcal{H}_2$  and  $\mathcal{L}_{\infty}$  norms. For a function  $G: \mathbb{C} \times \mathcal{P} \to \mathbb{C}^{p \times m}$ , such that  $G(\cdot; p)$  is analytic in the open right half-plane for all  $p \in \mathcal{P}$ , the  $\mathcal{H}_2 \otimes \mathcal{L}_2$  norm of G is

$$||G||_{\mathcal{H}_2 \otimes \mathcal{L}_2} := \left( \int_{\mathcal{P}} ||G(\cdot; \mathbf{p})||_{\mathcal{H}_2}^2 \, \mathrm{d}\mathbf{p} \right)^{1/2}. \tag{10}$$

Under Theorem 2.2,  $||H||_{\mathcal{H}_2 \otimes \mathcal{L}_2} < \infty$ , as  $||H(\cdot; \mathbf{p})||_{\mathcal{H}_2}$  is bounded for all  $\mathbf{p} \in \mathcal{P}$  and  $\mathcal{P}$  has finite measure. The  $\mathcal{L}_{\infty} \otimes \mathcal{L}_2$  norm of a vector-valued function  $v : \mathbb{R} \times \mathcal{P} \to \mathbb{R}^p$  is

$$\|v\|_{\mathcal{L}_{\infty}\otimes\mathcal{L}_{2}} := \left(\int_{\mathcal{P}} \|v(\cdot; \mathsf{p})\|_{\mathcal{L}_{\infty}}^{2} d\mathsf{p}\right)^{1/2}.$$

Using (6) for  $H(\cdot; \mathbf{p})$  and  $\widehat{H}(\cdot; \mathbf{p})$ , it follows that the output error, as measured by the  $\mathcal{L}_{\infty} \otimes \mathcal{L}_{2}$  norm, is bounded by the  $\mathcal{H}_{2} \otimes \mathcal{L}_{2}$  norm of the error system (9), i.e.,

$$\|y - \widehat{y}\|_{\mathcal{L}_{\infty} \otimes \mathcal{L}_{2}} \le \|H - \widehat{H}\|_{\mathcal{H}_{2} \otimes \mathcal{L}_{2}} \|u\|_{\mathcal{L}_{2}}. \tag{11}$$

If  $\widehat{E}(\mathsf{p})$  is invertible and  $\widehat{\Sigma}_{\mathcal{P}}$  is asymptotically stable for all  $\mathsf{p} \in \mathcal{P}$ , then  $\|H - \widehat{H}\|_{\mathcal{H}_2 \otimes \mathcal{L}_2}$  is ensured to be finite. The inequality in (11) immediately leads to the following optimization problem for  $\mathcal{H}_2 \otimes \mathcal{L}_2$  parametric MOR

$$\min_{\widehat{E},\widehat{A},\widehat{B},\widehat{C}} \|H - \widehat{H}\|_{\mathcal{H}_2 \otimes \mathcal{L}_2}.$$

Since optimizing over the space of all possible functions is clearly impractical, in this paper we use the following widely used parameter-separable forms for matrix-valued functions. Specifically, we optimize over the following set of ROMs.

**Definition 2.3.** Let  $\widehat{e}_i, \widehat{a}_j, \widehat{b}_k, \widehat{c}_\ell \colon \mathcal{P} \to \mathbb{R}$ , for  $i \in \{1, \dots, q_{\widehat{E}}\} = [q_{\widehat{E}}], j \in [q_{\widehat{A}}], k \in [q_{\widehat{B}}],$  and  $\ell \in [q_{\widehat{C}}]$ , be given continuous functions. We define  $\mathcal{R}$  as the set of all ROMs whose matrix-valued functions have parameter-separable forms

$$\widehat{E}(\mathsf{p}) = \sum_{i=1}^{q_{\widehat{E}}} \widehat{e}_i(\mathsf{p}) \widehat{E}_i, \quad \widehat{A}(\mathsf{p}) = \sum_{i=1}^{q_{\widehat{A}}} \widehat{a}_j(\mathsf{p}) \widehat{A}_j, \quad \widehat{B}(\mathsf{p}) = \sum_{k=1}^{q_{\widehat{B}}} \widehat{b}_k(\mathsf{p}) \widehat{B}_k, \quad \widehat{C}(\mathsf{p}) = \sum_{\ell=1}^{q_{\widehat{C}}} \widehat{c}_\ell(\mathsf{p}) \widehat{C}_\ell, \qquad (12)$$

where  $\widehat{E}_i$ ,  $\widehat{A}_j \in \mathbb{R}^{r \times r}$ ,  $\widehat{B}_k \in \mathbb{R}^{r \times m}$ , and  $\widehat{C}_\ell \in \mathbb{R}^{p \times r}$  such that  $\widehat{E}(\mathsf{p})$  is invertible and  $\alpha(\widehat{A}(\mathsf{p}), \widehat{E}(\mathsf{p})) < 0$  for all  $\mathsf{p} \in \mathcal{P}$ .

Remark 2.4. Some comments on Theorem 2.3 are in order. First, we assume that the reducedorder matrix-valued functions (12) are cheap to evaluate for any  $p \in \mathcal{P}$ . Typically, this means that the scalar functions  $\hat{e}_i, \hat{a}_j, \hat{b}_k, \hat{c}_\ell$  are both few in number and inexpensive. Second, while  $\hat{E}(p)$  being invertible is satisfied generically (since almost all square matrices are invertible), we cannot expect the additional stability assumption also to hold generically. However, to state our upcoming FONC for  $\mathcal{H}_2 \otimes \mathcal{L}_2$  optimality in Section 3, it is convenient to define  $\mathcal{R}$  restricted to stable systems.

We are now ready to present the structured  $\mathcal{H}_2 \otimes \mathcal{L}_2$  optimization problem that we wish to solve in order to obtain a parametric reduced-order model for  $\Sigma_{\mathcal{P}}$ :

$$\min_{\widehat{\Sigma}_{\mathcal{P}} \in \mathcal{R}} \quad \mathcal{J}(\widehat{\Sigma}_{\mathcal{P}}), \tag{13}$$

where  $\mathcal{R}$  is from Theorem 2.3 and  $\mathcal{J}(\widehat{\Sigma}_{\mathcal{P}}) := \|H - \widehat{H}\|_{\mathcal{H}_2 \otimes \mathcal{L}_2}^2$ . We use the squared  $\mathcal{H}_2 \otimes \mathcal{L}_2$  error, as it is more convenient for deriving the respective gradients.

**Remark 2.5.** Note that (13), due to the restriction of  $\widehat{\Sigma}_{\mathcal{P}} \in \mathcal{R}$ , is actually a constrained optimization problem, i.e., per the stability assumption in Theorem 2.3 defining  $\mathcal{R}$ , a valid minimizer of (13) must also be a stable system. In Section 6, we explain how we satisfy this constraint algorithmically.

Naturally, if a FOM has matrix-valued functions of the form as in (12) with the same scalar functions, then any ROM  $\widehat{\Sigma}_{\mathcal{P}} \in \mathcal{R}$  automatically preserves this structure. However, the method that we propose in this paper does not require that a FOM has matrix-valued functions with a short parameter-separable form; the FOM need only satisfy the conditions given in Theorem 2.2. In contrast, projection-based methods require approximating the full-order matrices, e.g., using empirical interpolation (see [7, Chapter 2]), to be able to efficiently evaluate reduced matrix-valued functions.

Analogously to (7) for the  $\mathcal{H}_2$  norm, the  $\mathcal{H}_2 \otimes \mathcal{L}_2$  norm (10) can be written as

$$\|H - \widehat{H}\|_{\mathcal{H}_2 \otimes \mathcal{L}_2}^2 = \int_{\mathcal{P}} \operatorname{tr} \left( C_e(\mathsf{p}) P_e(\mathsf{p}) C_e(\mathsf{p})^\mathsf{T} \right) d\mathsf{p} = \int_{\mathcal{P}} \operatorname{tr} \left( B_e(\mathsf{p})^\mathsf{T} Q_e(\mathsf{p}) B_e(\mathsf{p}) \right) d\mathsf{p}, \tag{14}$$

where for each  $p \in \mathcal{P}$ ,  $P_e(p) = P_e(p)^T$  and  $Q_e(p) = Q_e(p)^T$ , both in  $\mathbb{R}^{(n+r)\times(n+r)}$ , respectively define the controllability  $(P_e(p))$  and observability  $(E_e(p)^TQ_e(p)E_e(p))$  Gramians of the error system (9). Thus,

$$0 = A_e(\mathbf{p})P_e(\mathbf{p})E_e(\mathbf{p})^\mathsf{T} + E_e(\mathbf{p})P_e(\mathbf{p})A_e(\mathbf{p})^\mathsf{T} + B_e(\mathbf{p})B_e(\mathbf{p})^\mathsf{T}, \tag{15a}$$

$$0 = A_e(\mathbf{p})^\mathsf{T} Q_e(\mathbf{p}) E_e(\mathbf{p}) + E_e(\mathbf{p})^\mathsf{T} Q_e(\mathbf{p}) A_e(\mathbf{p}) + C_e(\mathbf{p})^\mathsf{T} C_e(\mathbf{p}), \tag{15b}$$

where  $P_e(\mathsf{p}) = \begin{bmatrix} P(\mathsf{p}) & \widetilde{P}(\mathsf{p}) \\ \widetilde{P}(\mathsf{p})^\mathsf{T} & \widehat{P}(\mathsf{p}) \end{bmatrix}$  has blocks  $P(\mathsf{p}) = P(\mathsf{p})^\mathsf{T} \in \mathbb{R}^{n \times n}$ ,  $\widehat{P}(\mathsf{p}) = \widehat{P}(\mathsf{p})^\mathsf{T} \in \mathbb{R}^{r \times r}$ , and  $\widetilde{P}(\mathsf{p}) \in \mathbb{R}^{n \times r}$ , and

$$0 = A(\mathbf{p})P(\mathbf{p})E(\mathbf{p})^{\mathsf{T}} + E(\mathbf{p})P(\mathbf{p})A(\mathbf{p})^{\mathsf{T}} + B(\mathbf{p})B(\mathbf{p})^{\mathsf{T}}, \tag{16a}$$

$$0 = A(\mathbf{p})\widetilde{P}(\mathbf{p})\widehat{E}(\mathbf{p})^{\mathsf{T}} + E(\mathbf{p})\widetilde{P}(\mathbf{p})\widehat{A}(\mathbf{p})^{\mathsf{T}} + B(\mathbf{p})\widehat{B}(\mathbf{p})^{\mathsf{T}}, \tag{16b}$$

$$0 = \widehat{A}(\mathbf{p})\widehat{P}(\mathbf{p})\widehat{E}(\mathbf{p})^{\mathsf{T}} + \widehat{E}(\mathbf{p})\widehat{P}(\mathbf{p})\widehat{A}(\mathbf{p})^{\mathsf{T}} + \widehat{B}(\mathbf{p})\widehat{B}(\mathbf{p})^{\mathsf{T}}. \tag{16c}$$

Correspondingly,  $Q_e(\mathsf{p}) = \begin{bmatrix} Q(\mathsf{p}) & \widetilde{Q}(\mathsf{p}) \\ \widetilde{Q}(\mathsf{p})^\mathsf{T} & \widehat{Q}(\mathsf{p}) \end{bmatrix}$  has blocks  $Q(\mathsf{p}) = Q(\mathsf{p})^\mathsf{T} \in \mathbb{R}^{n \times n}$ ,  $\widehat{Q}(\mathsf{p}) = \widehat{Q}(\mathsf{p})^\mathsf{T} \in \mathbb{R}^{r \times r}$ , and  $\widetilde{Q}(\mathsf{p}) \in \mathbb{R}^{n \times r}$ , and

$$0 = A(\mathbf{p})^{\mathsf{T}} Q(\mathbf{p}) E(\mathbf{p}) + E(\mathbf{p})^{\mathsf{T}} Q(\mathbf{p}) A(\mathbf{p}) + C(\mathbf{p})^{\mathsf{T}} C(\mathbf{p}), \tag{17a}$$

$$0 = A(\mathbf{p})^{\mathsf{T}} \widetilde{Q}(\mathbf{p}) \widehat{E}(\mathbf{p}) + E(\mathbf{p})^{\mathsf{T}} \widetilde{Q}(\mathbf{p}) \widehat{A}(\mathbf{p}) - C(\mathbf{p})^{\mathsf{T}} \widehat{C}(\mathbf{p}), \tag{17b}$$

$$0 = \widehat{A}(\mathsf{p})^{\mathsf{T}}\widehat{Q}(\mathsf{p})\widehat{E}(\mathsf{p}) + \widehat{E}(\mathsf{p})^{\mathsf{T}}\widehat{Q}(\mathsf{p})\widehat{A}(\mathsf{p}) + \widehat{C}(\mathsf{p})^{\mathsf{T}}\widehat{C}(\mathsf{p}). \tag{17c}$$

Note that these blocks above, due to (14), will play a key role in our new FONC in Section 3, and by Theorem 2.2, these matrix-valued functions are continuous and bounded over  $\mathcal{P}$ .

## 2.3 Fréchet differentiability

For our theoretical results in Section 3, we need the following functional analysis definitions and results, which follow [30, Chapter 4] and [9, Chapters 3, 6, and 8]. Let L(X,Y) denote the class of all bounded linear operators  $A: X \to Y$  and f(x) = o(||x||) denote that  $f(x)/||x|| \to 0$  as  $x \to 0$ .

**Definition 2.6.** Let X and Y be normed vector spaces,  $U \subseteq X$  open, and  $f: U \to Y$  a function. The function f is said to be Fréchet differentiable at  $x \in U$  if there exists an operator  $Df(x) \in L(X,Y)$  such that

$$f(x+h) = f(x) + Df(x)h + o(||h||),$$

for all h in some neighborhood of zero. The operator Df(x) is called the Fréchet derivative of f at x.

**Definition 2.7.** Let X be a Hilbert space with inner product  $\langle \cdot, \cdot \rangle_X$ ,  $U \subseteq X$  open, and  $f \colon U \to \mathbb{R}$  a function. Further, let f be Fréchet differentiable at  $x \in U$ . The Riesz representative of Df(x), i.e., the element  $a \in X$  such that

$$Df(x)h = \langle a, h \rangle_X,$$

for all  $h \in X$ , is called the gradient of f at x and is denoted by  $\nabla f(x)$ .

**Definition 2.8.** Let X, Y, and Z be normed vector spaces,  $U \subset X \times Y$  open, and  $f: U \to Z$  a function. Let y be fixed and set g(x) = f(x,y). If g is Fréchet differentiable at x, then we define the partial Fréchet derivative of f at (x,y) with respect to x to be  $D_x f(x,y) = Dg(x)$ . The derivative  $D_y f(x,y)$  and partial gradients are defined analogously.

## **3** First-order analysis of the squared $\mathcal{H}_2 \otimes \mathcal{L}_2$ norm

Our main theoretical result, given in the following theorem, establishes the gradient of the squared  $\mathcal{H}_2 \otimes \mathcal{L}_2$  norm of the error system (9) with respect to the reduced-order matrices given by (12). This in turn directly establishes FONC for  $\mathcal{H}_2 \otimes \mathcal{L}_2$  optimality, which we describe in Theorem 3.5 at the end of this section.

**Theorem 3.1** (Gradient). Let Theorem 2.2 hold. Furthermore, let H and  $\widehat{H}$  be transfer functions for systems  $\Sigma_{\mathcal{P}}$  (1) and  $\widehat{\Sigma}_{\mathcal{P}}$  (2), respectively, with  $\widehat{\Sigma}_{\mathcal{P}} \in \mathcal{R}$ . Then the gradient of  $\mathcal{J}(\widehat{\Sigma}_{\mathcal{P}}) = \|H - \widehat{H}\|_{\mathcal{H}_2 \otimes \mathcal{L}_2}^2$  with respect to the fixed matrices defining (12) is given by

$$\begin{split} \nabla_{\widehat{E}_{i}}\mathcal{J}\big(\widehat{\Sigma}_{\mathcal{P}}\big) &= 2\int_{\mathcal{P}}\widehat{e}_{i}(\mathsf{p})\Big(\widehat{Q}(\mathsf{p})^{\mathsf{T}}\widehat{A}(\mathsf{p})\widehat{P}(\mathsf{p}) + \widetilde{Q}(\mathsf{p})^{\mathsf{T}}A(\mathsf{p})\widetilde{P}(\mathsf{p})\Big)\,\mathrm{d}\mathsf{p}, \qquad i \in [q_{\widehat{E}}], \\ \nabla_{\widehat{A}_{j}}\mathcal{J}\big(\widehat{\Sigma}_{\mathcal{P}}\big) &= 2\int_{\mathcal{P}}\widehat{a}_{j}(\mathsf{p})\Big(\widehat{Q}(\mathsf{p})^{\mathsf{T}}\widehat{E}(\mathsf{p})\widehat{P}(\mathsf{p}) + \widetilde{Q}(\mathsf{p})^{\mathsf{T}}E(\mathsf{p})\widetilde{P}(\mathsf{p})\Big)\,\mathrm{d}\mathsf{p}, \qquad j \in [q_{\widehat{A}}], \\ \nabla_{\widehat{B}_{k}}\mathcal{J}\big(\widehat{\Sigma}_{\mathcal{P}}\big) &= 2\int_{\mathcal{P}}\widehat{b}_{k}(\mathsf{p})\Big(\widehat{Q}(\mathsf{p})^{\mathsf{T}}\widehat{B}(\mathsf{p}) + \widetilde{Q}(\mathsf{p})^{\mathsf{T}}B(\mathsf{p})\Big)\,\mathrm{d}\mathsf{p}, \qquad k \in [q_{\widehat{B}}], \\ \nabla_{\widehat{C}_{\ell}}\mathcal{J}\big(\widehat{\Sigma}_{\mathcal{P}}\big) &= 2\int_{\mathcal{P}}\widehat{c}_{\ell}(\mathsf{p})\Big(\widehat{C}(\mathsf{p})\widehat{P}(\mathsf{p}) - C(\mathsf{p})\widetilde{P}(\mathsf{p})\Big)\,\mathrm{d}\mathsf{p}, \qquad \ell \in [q_{\widehat{C}}], \end{split}$$

with  $\widetilde{P}$ ,  $\widehat{P}$  as in (16b) and (16c) and  $\widetilde{Q}$ ,  $\widehat{Q}$  as in (17b) and (17c).

Per Theorem 2.1, recall that Wilson derived the analogous FONC for  $\mathcal{H}_2$ -optimal MOR when  $E = I_n$  and  $\hat{E} = I_r$ . To prove Theorem 3.1, we first need several intermediate results. To this end, we now respectively generalize [27, Lemma 3.2 and Theorem 3.3] to the case of general invertible E and  $\hat{E}$  matrices.

**Lemma 3.2.** Let  $A, E \in \mathbb{R}^{n \times n}$ ,  $\widehat{A}, \widehat{E} \in \mathbb{R}^{r \times r}$ , and  $B, C \in \mathbb{R}^{n \times r}$ . If  $M, N \in \mathbb{R}^{n \times r}$  solve the Sylvester equations

$$0 = AM\widehat{E}^{\mathsf{T}} + EM\widehat{A}^{\mathsf{T}} + B, \quad 0 = A^{\mathsf{T}}N\widehat{E} + E^{\mathsf{T}}N\widehat{A} + C, \tag{18}$$

then  $\operatorname{tr}(B^{\mathsf{T}}N) = \operatorname{tr}(C^{\mathsf{T}}M)$ .

*Proof.* By substituting in B from (18) into  $tr(B^{\mathsf{T}}N)$  and using the linearity and cyclic permutation properties of the trace, we have that

$$\operatorname{tr}(B^{\mathsf{T}}N) = \operatorname{tr}\left(-\left(AM\widehat{E}^{\mathsf{T}} + EM\widehat{A}^{\mathsf{T}}\right)^{\mathsf{T}}N\right) = \operatorname{tr}\left(-\left(\widehat{E}M^{\mathsf{T}}A^{\mathsf{T}}N + \widehat{A}M^{\mathsf{T}}E^{\mathsf{T}}N\right)\right)$$
$$= \operatorname{tr}\left(-\left(A^{\mathsf{T}}N\widehat{E} + E^{\mathsf{T}}N\widehat{A}\right)M^{\mathsf{T}}\right) = \operatorname{tr}\left(C^{\mathsf{T}}M\right).$$

**Theorem 3.3.** Let  $\Sigma$  and  $\widehat{\Sigma}$ , as in (3) and (4), respectively with transfer functions H and  $\widehat{H}$ , have invertible E and  $\widehat{E}$  matrices and be asymptotically stable non-parametric systems. Then, for  $\widetilde{\mathcal{J}}(\widehat{\Sigma}) := \|H - \widehat{H}\|_{\mathcal{H}}^2$ , the following hold

$$\nabla_{\widehat{E}}\widetilde{\mathcal{J}}(\widehat{\Sigma}) = 2(\widehat{Q}^{\mathsf{T}}\widehat{A}\widehat{P} + \widetilde{Q}^{\mathsf{T}}A\widetilde{P}), \tag{19a}$$

$$\nabla_{\widehat{A}}\widetilde{\mathcal{J}}(\widehat{\Sigma}) = 2(\widehat{Q}^{\mathsf{T}}\widehat{E}\widehat{P} + \widetilde{Q}^{\mathsf{T}}E\widetilde{P}), \tag{19b}$$

$$\nabla_{\widehat{B}}\widetilde{\mathcal{J}}(\widehat{\Sigma}) = 2(\widehat{Q}^{\mathsf{T}}\widehat{B} + \widetilde{Q}^{\mathsf{T}}B), \tag{19c}$$

$$\nabla_{\widehat{C}}\widetilde{\mathcal{J}}(\widehat{\Sigma}) = 2(\widehat{C}\widehat{P} - C\widetilde{P}). \tag{19d}$$

*Proof.* We only derive the gradient with respect to  $\widehat{E}$ , as the other gradients follow with similar arguments. Given non-parametric systems (3) and (4), for the duration of this proof we redefine (17) as its non-parametric analogue, i.e., we remove the dependency on p from its equations. Then, via (7), we have the following formulation of the squared  $\mathcal{H}_2$  error

$$\widetilde{\mathcal{J}}(\widehat{\Sigma}) = \operatorname{tr}\left(B^{\mathsf{T}}QB + 2B^{\mathsf{T}}\widetilde{Q}\widehat{B} + \widehat{B}^{\mathsf{T}}\widehat{Q}\widehat{B}\right),$$

where matrices Q,  $\widetilde{Q}$ , and  $\widehat{Q}$  are from (again, the non-parametric analogues of) (17). Analogous to the proof of [27, Theorem 3.3], a perturbation in  $\widehat{E}$  leads to perturbations in  $\widetilde{Q}$  and  $\widehat{Q}$ . Thus, by respectively replacing  $\widehat{E}$  and  $\widetilde{Q}$  in the Sylvester equation (17b) with  $\widehat{E} + \Delta_1$  and  $\widetilde{Q} + \Delta_2$ , and then using equality (17b), it follows that

$$0 = A^{\mathsf{T}} \Big( \widetilde{Q} + \Delta_2 \Big) \Big( \widehat{E} + \Delta_1 \Big) + E^{\mathsf{T}} \Big( \widetilde{Q} + \Delta_2 \Big) \widehat{A} - C^{\mathsf{T}} \widehat{C}$$

$$= \Big( A^{\mathsf{T}} \widetilde{Q} \widehat{E} + E^{\mathsf{T}} \widetilde{Q} \widehat{A} - C^{\mathsf{T}} \widehat{C} \Big) + A^{\mathsf{T}} \widetilde{Q} \Delta_1 + A^{\mathsf{T}} \Delta_2 \widehat{E} + E^{\mathsf{T}} \Delta_2 \widehat{A} + A^{\mathsf{T}} \Delta_2 \Delta_1$$

$$= A^{\mathsf{T}} \widetilde{Q} \Delta_1 + A^{\mathsf{T}} \Delta_2 \widehat{E} + E^{\mathsf{T}} \Delta_2 \widehat{A} + o(\|\Delta_1\|_{\mathsf{F}}). \tag{20}$$

Correspondingly, respectively replacing  $\widehat{E}$  and  $\widehat{Q}$  in the Lyapunov equation (17c) with  $\widehat{E} + \Delta_1$  and  $\widehat{Q} + \Delta_3$  and then using equality (17c), we have that

$$0 = \widehat{A}^{\mathsf{T}} \Big( \widehat{Q} + \Delta_3 \Big) \Big( \widehat{E} + \Delta_1 \Big) + \Big( \widehat{E} + \Delta_1 \Big)^{\mathsf{T}} \Big( \widehat{Q} + \Delta_3 \Big) \widehat{A} + \widehat{C}^{\mathsf{T}} \widehat{C}$$

$$= \Big( \widehat{A}^{\mathsf{T}} \widehat{Q} \widehat{E} + \widehat{E}^{\mathsf{T}} \widehat{Q} \widehat{A} + \widehat{C}^{\mathsf{T}} \widehat{C} \Big) + \widehat{A}^{\mathsf{T}} \widehat{Q} \Delta_1 + \widehat{A}^{\mathsf{T}} \Delta_3 \widehat{E} + \widehat{E}^{\mathsf{T}} \Delta_3 \widehat{A} + \Delta_1^{\mathsf{T}} \widehat{Q} \widehat{A}$$

$$+ \widehat{A}^{\mathsf{T}} \Delta_3 \Delta_1 + \Delta_1^{\mathsf{T}} \Delta_3 \widehat{A}$$

$$= \widehat{A}^{\mathsf{T}} \widehat{Q} \Delta_1 + \Delta_1^{\mathsf{T}} \widehat{Q} \widehat{A} + \widehat{A}^{\mathsf{T}} \Delta_3 \widehat{E} + \widehat{E}^{\mathsf{T}} \Delta_3 \widehat{A} + o(\|\Delta_1\|_{\mathsf{F}}).$$

$$(21)$$

Now consider the perturbed system  $\widehat{\Sigma}_{\Delta} := (\widehat{E} + \Delta_1, \widehat{A}, \widehat{B}, \widehat{C})$ . This perturbation to  $\widehat{E}$  results in the following perturbations  $\widehat{E} + \Delta_1$ ,  $\widetilde{Q} + \Delta_2$ , and  $\widehat{Q} + \Delta_3$  in  $\widetilde{\mathcal{J}}$ , and so

$$\widetilde{\mathcal{J}}(\widehat{\Sigma}_{\Delta}) = \operatorname{tr}\left(B^{\mathsf{T}}QB + 2B^{\mathsf{T}}\left(\widetilde{Q} + \Delta_{2}\right)\widehat{B} + \widehat{B}^{\mathsf{T}}\left(\widehat{Q} + \Delta_{3}\right)\widehat{B}\right)$$

$$= \widetilde{\mathcal{J}}(\widehat{\Sigma}) + \operatorname{tr}\left(2B^{\mathsf{T}}\Delta_{2}\widehat{B} + \widehat{B}^{\mathsf{T}}\Delta_{3}\widehat{B}\right). \tag{22}$$

In order to obtain (19a), we first rewrite the second summand of (22) as an inner product as follows. By applying Theorem 3.2 to Sylvester equations (16b) (solving for  $\tilde{P}$ ) and (20) (solving for  $\Delta_2$ ) and then using properties of the trace, we have

$$2\operatorname{tr}(\widehat{B}B^{\mathsf{T}}\Delta_{2}) = 2\operatorname{tr}(\Delta_{1}^{\mathsf{T}}\widetilde{Q}^{\mathsf{T}}A\widetilde{P}) + o(\|\Delta_{1}\|_{F}). \tag{23}$$

By applying the same procedure to Lyapunov equations (16c) and (21), we obtain

$$\operatorname{tr}\left(\widehat{B}\widehat{B}^{\mathsf{T}}\Delta_{3}\right) = 2\operatorname{tr}\left(\Delta_{1}^{\mathsf{T}}\widehat{Q}^{\mathsf{T}}\widehat{A}\widehat{P}\right) + o(\|\Delta_{1}\|_{F}). \tag{24}$$

Plugging (23) and (24) into (22) yields

$$\begin{aligned} \operatorname{tr} \Big( 2B^{\mathsf{T}} \Delta_2 \widehat{B} + \widehat{B}^{\mathsf{T}} \Delta_3 \widehat{B} \Big) &= 2 \operatorname{tr} \Big( \Delta_1^{\mathsf{T}} \widetilde{Q}^{\mathsf{T}} A \widetilde{P} \Big) + 2 \operatorname{tr} \Big( \Delta_1^{\mathsf{T}} \widehat{Q}^{\mathsf{T}} \widehat{A} \widehat{P} \Big) + o(\|\Delta_1\|_{\mathrm{F}}) \\ &= \operatorname{tr} \Big( 2 \Big( \widetilde{P}^{\mathsf{T}} A^{\mathsf{T}} \widetilde{Q} + \widehat{P}^{\mathsf{T}} \widehat{A}^{\mathsf{T}} \widehat{Q} \Big) \Delta_1 \Big) + o(\|\Delta_1\|_{\mathrm{F}}) \\ &= \Big\langle 2 \Big( \widetilde{Q}^{\mathsf{T}} A \widetilde{P} + \widehat{Q}^{\mathsf{T}} \widehat{A} \widehat{P} \Big), \Delta_1 \Big\rangle_{\mathrm{F}} + o(\|\Delta_1\|_{\mathrm{F}}). \end{aligned}$$

The gradient (19a) follows using Theorem 2.7.

The following corollary (of Theorem 3.3) will be useful in proving Theorem 3.1.

Corollary 3.4. Let  $\Sigma$  and  $\widehat{\Sigma}$ , as in (3) and (4), respectively with transfer functions H and  $\widehat{H}$ , have invertible E and  $\widehat{E}$  matrices and be asymptotically stable non-parametric systems. Furthermore, let the reduced-order matrices be decomposed as  $\widehat{E} = \widehat{e}_1 \widehat{E}_1 + \widehat{E}_2$ ,  $\widehat{A} = \widehat{a}_1 \widehat{A}_1 + \widehat{A}_2$ ,  $\widehat{B} = \widehat{b}_1 \widehat{B}_1 + \widehat{B}_2$ , and  $\widehat{C} = \widehat{c}_1 \widehat{C}_1 + \widehat{C}_2$ , where  $\widehat{e}_1, \widehat{a}_1, \widehat{b}_1, \widehat{c}_1 \in \mathbb{R}$ . Then, for  $\widehat{\mathcal{J}}(\widehat{\Sigma}) := \|H - \widehat{H}\|_{\mathcal{H}_2}^2$ ,

$$\begin{split} &\nabla_{\widehat{E}_{1}}\widetilde{\mathcal{J}}(\widehat{\Sigma}) = 2\widehat{e}_{1}\Big(\widehat{Q}^{\mathsf{T}}\widehat{A}\widehat{P} + \widetilde{Q}^{\mathsf{T}}A\widetilde{P}\Big), \\ &\nabla_{\widehat{A}_{1}}\widetilde{\mathcal{J}}(\widehat{\Sigma}) = 2\widehat{a}_{1}\Big(\widehat{Q}^{\mathsf{T}}\widehat{E}\widehat{P} + \widetilde{Q}^{\mathsf{T}}E\widetilde{P}\Big), \\ &\nabla_{\widehat{B}_{1}}\widetilde{\mathcal{J}}(\widehat{\Sigma}) = 2\widehat{b}_{1}\Big(\widehat{Q}^{\mathsf{T}}\widehat{B} + \widetilde{Q}^{\mathsf{T}}B\Big), \\ &\nabla_{\widehat{C}_{1}}\widetilde{\mathcal{J}}(\widehat{\Sigma}) = 2\widehat{c}_{1}\Big(\widehat{C}\widehat{P} - C\widetilde{P}\Big), \end{split}$$

using the convention that  $\widetilde{\mathcal{J}}$  is a function of  $\widehat{E}_1$ ,  $\widehat{A}_1$ ,  $\widehat{B}_1$ , and  $\widehat{C}_1$ .

As we now show, the proof of Theorem 3.1 follows from our results above.

*Proof of Theorem 3.1.* We only give the proof for the gradient with respect to  $\widehat{E}_i$ , as the others follow similarly. We note that  $\widehat{E}(\mathbf{p})$  can be written as

$$\widehat{E}(\mathbf{p}) = \widehat{e}_i(\mathbf{p})\widehat{E}_i + \sum_{\substack{j=1\\j\neq i}}^{q_{\widehat{E}}} \widehat{e}_j(\mathbf{p})\widehat{E}_j = \widehat{e}_i(\mathbf{p})\widehat{E}_i + \widetilde{E}(\mathbf{p}),$$

where  $\widetilde{E}(p) \in \mathbb{R}^{r \times r}$  does not depend on  $\widehat{E}_i$ , and so we have the same structure of the matrix  $\widehat{E}(p)$  as in Theorem 3.4. Respectively using the Leibniz rule and Theorem 3.4 to obtain the second and third equalities below, we conclude the proof via

$$\begin{split} \nabla_{\widehat{E}_i} \mathcal{J} \big( \widehat{\Sigma}_{\mathcal{P}} \big) &= \nabla_{\widehat{E}_i} \int_{\mathcal{P}} \left\| H(\cdot; \mathsf{p}) - \widehat{H}(\cdot; \mathsf{p}) \right\|_{\mathcal{H}_2}^2 \mathrm{d} \mathsf{p} = \int_{\mathcal{P}} \nabla_{\widehat{E}_i} \left\| H(\cdot; \mathsf{p}) - \widehat{H}(\cdot; \mathsf{p}) \right\|_{\mathcal{H}_2}^2 \mathrm{d} \mathsf{p} \\ &= 2 \int_{\mathcal{P}} \widehat{e}_i(\mathsf{p}) \Big( \widehat{Q}(\mathsf{p})^\mathsf{T} \widehat{A}(\mathsf{p}) \widehat{P}(\mathsf{p}) + \widetilde{Q}(\mathsf{p})^\mathsf{T} A(\mathsf{p}) \widetilde{P}(\mathsf{p}) \Big) \, \mathrm{d} \mathsf{p}. \end{split}$$

The  $\mathcal{H}_2 \otimes \mathcal{L}_2$  FONC, which we first described in [15], is a direct consequence of Theorem 3.1. Hence, we restate the  $\mathcal{H}_2 \otimes \mathcal{L}_2$  FONC here as the following corollary.

Corollary 3.5 (FONC). Let Theorem 2.2 hold. Furthermore, let  $\widehat{\Sigma}_{\mathcal{P}} \in \mathcal{R}$  be a structured  $\mathcal{H}_2 \otimes \mathcal{L}_2$ optimal ROM for  $\Sigma_{\mathcal{P}}$  (1), recalling that  $\widehat{\Sigma}_{\mathcal{P}}$  has matrix-valued functions in parameter-separable form as in (12). Then

$$0 = \int_{\mathcal{P}} \widehat{e}_i(\mathsf{p}) \left( \widehat{Q}(\mathsf{p})^\mathsf{T} \widehat{A}(\mathsf{p}) \widehat{P}(\mathsf{p}) + \widetilde{Q}(\mathsf{p})^\mathsf{T} A(\mathsf{p}) \widetilde{P}(\mathsf{p}) \right) d\mathsf{p}, \qquad i \in [q_{\widehat{E}}], \tag{25a}$$

$$0 = \int_{\mathcal{P}} \widehat{a}_j(\mathsf{p}) \Big( \widehat{Q}(\mathsf{p})^\mathsf{T} \widehat{E}(\mathsf{p}) \widehat{P}(\mathsf{p}) + \widetilde{Q}(\mathsf{p})^\mathsf{T} E(\mathsf{p}) \widetilde{P}(\mathsf{p}) \Big) \, \mathrm{d}\mathsf{p}, \qquad j \in [q_{\widehat{A}}], \tag{25b}$$

$$0 = \int_{\mathcal{P}} \widehat{b}_k(\mathsf{p}) \left( \widehat{Q}(\mathsf{p})^\mathsf{T} \widehat{B}(\mathsf{p}) + \widetilde{Q}(\mathsf{p})^\mathsf{T} B(\mathsf{p}) \right) d\mathsf{p}, \qquad k \in [q_{\widehat{B}}], \tag{25c}$$

$$0 = \int_{\mathcal{P}} \widehat{c}_{\ell}(\mathsf{p}) \Big( \widehat{C}(\mathsf{p}) \widehat{P}(\mathsf{p}) - C(\mathsf{p}) \widetilde{P}(\mathsf{p}) \Big) \, \mathrm{d}\mathsf{p}, \qquad \qquad \ell \in [q_{\widehat{C}}], \tag{25d}$$

with  $\widetilde{P}$ ,  $\widehat{P}$  as in (16b) and (16c) and  $\widetilde{Q}$ ,  $\widehat{Q}$  as in (17b) and (17c).

Due to the similarity of the equations in (25) with the Wilson conditions (8) for non-parametric systems, in [15] (and later in [19, Theorem 6.11]) we referred to (25) as Wilson-type optimality conditions, but for conciseness, we use FONC in this paper.

## 4 Comparison to related work

We now compare our results in Theorem 3.5 with earlier results of Baur et al. [3], Grimm [13], and Petersson [22].

## 4.1 Parametric B, C optimality results of Baur et al

A special case of  $\mathcal{H}_2 \otimes \mathcal{L}_2$ -optimal parametric MOR is considered in [3, Section 5.1], where the FOM

$$E\dot{x}(t;\mathbf{p}) = Ax(t;\mathbf{p}) + B(\mathbf{p})u(t),$$
  

$$y(t;\mathbf{p}) = C(\mathbf{p})x(t;\mathbf{p}),$$
(26)

is a single-input, single-output system,  $E, A \in \mathbb{R}^{n \times n}$  are constant matrices, and for  $p = (p_1, p_2)$ and  $p_1, p_2 \in [0, 1]$ , we have the following parameter-separable forms:

$$B(\mathbf{p}) = B_1 + \mathbf{p}_1 B_2 \in \mathbb{R}^{n \times 1} \quad \text{and} \quad C(\mathbf{p}) = C_1 + \mathbf{p}_2 C_2 \in \mathbb{R}^{1 \times n}. \tag{27}$$

The ROM is assumed to have the same structure as the FOM, i.e.,

$$\widehat{E}\dot{\widehat{x}}(t;\mathbf{p}) = \widehat{A}\widehat{x}(t;\mathbf{p}) + \widehat{B}(\mathbf{p})u(t),$$

$$\widehat{y}(t;\mathbf{p}) = \widehat{C}(\mathbf{p})\widehat{x}(t;\mathbf{p}),$$
(28)

where  $\widehat{E}$ ,  $\widehat{A} \in \mathbb{R}^{r \times r}$  and

$$\widehat{B}(\mathbf{p}) = \widehat{B}_1 + \mathbf{p}_1 \widehat{B}_2 \in \mathbb{R}^{r \times 1} \quad \text{and} \quad \widehat{C}(\mathbf{p}) = \widehat{C}_1 + \mathbf{p}_2 \widehat{C}_2 \in \mathbb{R}^{1 \times r}. \tag{29}$$

One of the main results of [3] states that, in this specific case, the  $\mathcal{H}_2 \otimes \mathcal{L}_2$  norm of the transfer function can be expressed as a weighted  $\mathcal{H}_2$  norm.

**Theorem 4.1** ([3, Theorem 5.1]). Let  $H(s; p) = C(p)(sE - A)^{-1}B(p)$  be the transfer function of (26) and  $p = (p_1, p_2)$  with  $p_1, p_2 \in [0, 1]$ . Define the auxiliary transfer function  $G(s) = \begin{bmatrix} C_1 \\ C_2 \end{bmatrix} (sE - A)^{-1} \begin{bmatrix} B_1 & B_2 \end{bmatrix}$  and  $L = \begin{bmatrix} \frac{1}{2} & \frac{1}{2\sqrt{3}} \\ \frac{1}{2} & \frac{1}{2\sqrt{3}} \end{bmatrix}$ . Then  $\|H\|_{\mathcal{H}_2 \otimes \mathcal{L}_2} = \|L^{\mathsf{T}}GL\|_{\mathcal{H}_2}$ .

To show how our FONC (25) generalize [3], first note that Theorem 4.1 also implies that ||H- $\widehat{H} \Big\|_{\mathcal{H}_2 \otimes \mathcal{L}_2} = \|L^\mathsf{T} G L - L^\mathsf{T} \widehat{G} L\|_{\mathcal{H}_2} \text{ holds, where transfer function } \widehat{G}(s) = \begin{bmatrix} \widehat{C}_1 \\ \widehat{C}_2 \end{bmatrix} (s \widehat{E} - \widehat{A})^{-1} [\widehat{B}_1 \widehat{B}_2].$ 

$$B_L = \begin{bmatrix} B_1 & B_2 \end{bmatrix} L, \quad \widehat{B}_L = \begin{bmatrix} \widehat{B}_1 & \widehat{B}_2 \end{bmatrix} L, \quad C_L = L^{\mathsf{T}} \begin{bmatrix} C_1 \\ C_2 \end{bmatrix}, \quad \text{and} \quad \widehat{C}_L = L^{\mathsf{T}} \begin{bmatrix} \widehat{C}_1 \\ \widehat{C}_2 \end{bmatrix},$$

and observing that  $L^{\mathsf{T}}GL$  and  $L^{\mathsf{T}}\widehat{G}L$  are, respectively, the transfer functions of  $(E, A, B_L, C_L)$  and  $(\widehat{E}, \widehat{A}, \widehat{B}_L, \widehat{C}_L)$ , it follows that the FONC for this setting are

$$0 = \widehat{Q}_L^{\mathsf{T}} \widehat{E} \widehat{P}_L + \widetilde{Q}_L^{\mathsf{T}} E \widetilde{P}_L,$$

$$0 = \widehat{Q}_L^{\mathsf{T}} \widehat{A} \widehat{P}_L + \widetilde{Q}_L^{\mathsf{T}} A \widetilde{P}_L,$$

$$0 = \widehat{Q}_L^{\mathsf{T}} \widehat{B}_L + \widetilde{Q}_L^{\mathsf{T}} B_L,$$

$$0 = \widehat{C}_L \widehat{P}_L - C_L \widetilde{P}_L,$$

$$(30)$$

with  $\widehat{P}_L$ ,  $\widetilde{P}_L$ ,  $\widehat{Q}_L$ ,  $\widetilde{Q}_L$  such that

$$0 = \widehat{A}\widehat{P}_{L}\widehat{E}^{\mathsf{T}} + \widehat{E}\widehat{P}_{L}\widehat{A}^{\mathsf{T}} + \widehat{B}_{L}\widehat{B}_{L}^{\mathsf{T}}, \qquad 0 = \widehat{A}^{\mathsf{T}}\widehat{Q}_{L}\widehat{E} + \widehat{E}^{\mathsf{T}}\widehat{Q}_{L}\widehat{A} + \widehat{C}_{L}^{\mathsf{T}}\widehat{C}_{L},$$

$$0 = A\widetilde{P}_{L}\widehat{E}^{\mathsf{T}} + E\widetilde{P}_{L}\widehat{A}^{\mathsf{T}} + B_{L}\widehat{B}_{L}^{\mathsf{T}}, \qquad 0 = A^{\mathsf{T}}\widetilde{Q}_{L}\widehat{E} + E^{\mathsf{T}}\widetilde{Q}_{L}\widehat{A} - C_{L}^{\mathsf{T}}\widehat{C}_{L}.$$

$$(31)$$

We now elaborate how the FONC (30) for the parametric MOR problem defined by (26)–(29) is actually a special case of our more general FONC (25).

**Lemma 4.2.** Let  $\Sigma_{\mathcal{P}}$  and  $\widehat{\Sigma}_{\mathcal{P}}$ , respectively, be asymptotically stable systems as in (26) and (28), E and  $\widehat{E}$  invertible, B, C,  $\widehat{B}$ , and  $\widehat{C}$  as in (27) and (29), and  $p = (p_1, p_2)$  with  $p_1, p_2 \in [0, 1]$ . Then  $\widetilde{P}$ ,  $\widehat{P}$ ,  $\widetilde{Q}$ , and  $\widehat{Q}$  satisfy

$$\widetilde{P}(\mathbf{p}) = \widetilde{P}_1 + \mathbf{p}_1 \widetilde{P}_2 + \mathbf{p}_1^2 \widetilde{P}_3, \tag{32a}$$

$$\widehat{P}(\mathsf{p}) = \widehat{P}_1 + \mathsf{p}_1 \widehat{P}_2 + \mathsf{p}_1^2 \widehat{P}_3, \tag{32b}$$

$$\widetilde{Q}(\mathbf{p}) = \widetilde{Q}_1 + \mathbf{p}_2 \widetilde{Q}_2 + \mathbf{p}_2^2 \widetilde{Q}_3, \tag{32c}$$

$$\widehat{Q}(\mathsf{p}) = \widehat{Q}_1 + \mathsf{p}_2 \widehat{Q}_2 + \mathsf{p}_2^2 \widehat{Q}_3, \tag{32d}$$

where for i = 1, 2, 3, matrices  $\widetilde{P}_i, \widetilde{Q}_i \in \mathbb{R}^{n \times r}$  are tall and skinny with

$$0 = A\widetilde{P}_1\widehat{E}^\mathsf{T} + E\widetilde{P}_1\widehat{A}^\mathsf{T} + B_1\widehat{B}_1^\mathsf{T},\tag{33a}$$

$$0 = A\widetilde{P}_2\widehat{E}^\mathsf{T} + E\widetilde{P}_2\widehat{A}^\mathsf{T} + B_1\widehat{B}_2^\mathsf{T} + B_2\widehat{B}_1^\mathsf{T},\tag{33b}$$

$$0 = A\widetilde{P}_3\widehat{E}^\mathsf{T} + E\widetilde{P}_3\widehat{A}^\mathsf{T} + B_2\widehat{B}_2^\mathsf{T},\tag{33c}$$

$$\begin{split} 0 &= \boldsymbol{A}^\mathsf{T} \widetilde{\boldsymbol{Q}}_1 \widehat{\boldsymbol{E}} + \boldsymbol{E}^\mathsf{T} \widetilde{\boldsymbol{Q}}_1 \widehat{\boldsymbol{A}} - \boldsymbol{C}_1^\mathsf{T} \widehat{\boldsymbol{C}}_1, \\ 0 &= \boldsymbol{A}^\mathsf{T} \widetilde{\boldsymbol{Q}}_2 \widehat{\boldsymbol{E}} + \boldsymbol{E}^\mathsf{T} \widetilde{\boldsymbol{Q}}_2 \widehat{\boldsymbol{A}} - \boldsymbol{C}_1^\mathsf{T} \widehat{\boldsymbol{C}}_2 - \boldsymbol{C}_2^\mathsf{T} \widehat{\boldsymbol{C}}_1, \\ 0 &= \boldsymbol{A}^\mathsf{T} \widetilde{\boldsymbol{Q}}_3 \widehat{\boldsymbol{E}} + \boldsymbol{E}^\mathsf{T} \widetilde{\boldsymbol{Q}}_3 \widehat{\boldsymbol{A}} - \boldsymbol{C}_2^\mathsf{T} \widehat{\boldsymbol{C}}_2, \end{split}$$

while  $\hat{P}_i, \hat{Q}_i \in \mathbb{R}^{r \times r}$  are small square matrices and

$$\begin{split} 0 &= \widehat{A}\widehat{P}_1\widehat{E}^\mathsf{T} + \widehat{E}\widehat{P}_1\widehat{A}^\mathsf{T} + \widehat{B}_1\widehat{B}_1^\mathsf{T}, & 0 &= \widehat{A}^\mathsf{T}\widehat{Q}_1\widehat{E} + \widehat{E}^\mathsf{T}\widehat{Q}_1\widehat{A} + \widehat{C}_1^\mathsf{T}\widehat{C}_1, \\ 0 &= \widehat{A}\widehat{P}_2\widehat{E}^\mathsf{T} + \widehat{E}\widehat{P}_2\widehat{A}^\mathsf{T} + \widehat{B}_1\widehat{B}_2^\mathsf{T} + \widehat{B}_2\widehat{B}_1^\mathsf{T}, & 0 &= \widehat{A}^\mathsf{T}\widehat{Q}_2\widehat{E} + \widehat{E}^\mathsf{T}\widehat{Q}_2\widehat{A} + \widehat{C}_1^\mathsf{T}\widehat{C}_2 + \widehat{C}_2^\mathsf{T}\widehat{C}_1, \\ 0 &= \widehat{A}\widehat{P}_3\widehat{E}^\mathsf{T} + \widehat{E}\widehat{P}_3\widehat{A}^\mathsf{T} + \widehat{B}_2\widehat{B}_2^\mathsf{T}, & 0 &= \widehat{A}^\mathsf{T}\widehat{Q}_3\widehat{E} + \widehat{E}^\mathsf{T}\widehat{Q}_3\widehat{A} + \widehat{C}_2^\mathsf{T}\widehat{C}_2. \end{split}$$

*Proof.* Substituting both B(p) from (27) and  $\widehat{B}(p)$  from (29) into (16b), we obtain that  $\widetilde{P}(p)$  is a solution of the following Sylvester equation

$$0 = AX\hat{E}^{\mathsf{T}} + EX\hat{A}^{\mathsf{T}} + B_1\hat{B}_1^{\mathsf{T}} + \mathsf{p}_1 \Big( B_1\hat{B}_2^{\mathsf{T}} + B_2\hat{B}_1^{\mathsf{T}} \Big) + \mathsf{p}_1^2 B_2\hat{B}_2^{\mathsf{T}}, \tag{34}$$

where  $X \in \mathbb{R}^{n \times n}$  is unknown. Meanwhile, by linearly combining (33a)–(33c), we see that  $\widetilde{P}_1 + \mathsf{p}_1 \widetilde{P}_2 + \mathsf{p}_1^2 \widetilde{P}_3$  also solves (34). We now explain that (34) in fact has a unique solution, and so  $\widetilde{P}(\mathsf{p}) = \widetilde{P}_1 + \mathsf{p}_1 \widetilde{P}_2 + \mathsf{p}_1^2 \widetilde{P}_3$ . For any given  $\mathsf{p} \in [0,1] \times [0,1]$ , by [8, Theorem 1], there exists a unique solution to (34) if the matrix pencils  $A - \lambda E$  and  $A = \lambda E = 0$  are nonsingular, both pencils must be regular. Furthermore, as we also assume that E = 0 and E = 0 where E = 0 are in the open right half-plane. The equalities in (32b)–(32d) are obtained in an analogous fashion.

**Theorem 4.3.** Let  $\Sigma_{\mathcal{P}}$  and  $\widehat{\Sigma}_{\mathcal{P}}$ , respectively, be asymptotically stable systems as in (26) and (28), E and  $\widehat{E}$  invertible, B, C,  $\widehat{B}$ , and  $\widehat{C}$  as in (27) and (29). Then, (30) is a special case of FONC (25).

*Proof.* Substituting the parameter-separable forms (32) into (25a), we obtain

$$0 = \int_{\mathcal{P}} \left( \widehat{Q}(\mathbf{p})^{\mathsf{T}} \widehat{A} \widehat{P}(\mathbf{p}) + \widetilde{Q}(\mathbf{p})^{\mathsf{T}} A \widetilde{P}(\mathbf{p}) \right) d\mathbf{p}$$

$$= \int_{0}^{1} \int_{0}^{1} \left( \left( \widehat{Q}_{1} + \mathbf{p}_{2} \widehat{Q}_{2} + \mathbf{p}_{2}^{2} \widehat{Q}_{3} \right)^{\mathsf{T}} \widehat{A} \left( \widehat{P}_{1} + \mathbf{p}_{1} \widehat{P}_{2} + \mathbf{p}_{1}^{2} \widehat{P}_{3} \right) + \left( \widetilde{Q}_{1} + \mathbf{p}_{2} \widetilde{Q}_{2} + \mathbf{p}_{2}^{2} \widetilde{Q}_{3} \right)^{\mathsf{T}} A \left( \widetilde{P}_{1} + \mathbf{p}_{1} \widetilde{P}_{2} + \mathbf{p}_{1}^{2} \widetilde{P}_{3} \right) \right) d\mathbf{p}_{1} d\mathbf{p}_{2}$$

$$= \widehat{W}^{\mathsf{T}} \widehat{A} \widehat{V} + \widetilde{W}^{\mathsf{T}} A \widetilde{V},$$

where

$$\widehat{V} := \widehat{P}_1 + \frac{1}{2}\widehat{P}_2 + \frac{1}{3}\widehat{P}_3, \qquad \widetilde{V} := \widetilde{P}_1 + \frac{1}{2}\widetilde{P}_2 + \frac{1}{3}\widetilde{P}_3, 
\widehat{W} := \widehat{Q}_1 + \frac{1}{2}\widehat{Q}_2 + \frac{1}{2}\widehat{Q}_3, \qquad \widetilde{W} := \widetilde{Q}_1 + \frac{1}{2}\widetilde{Q}_2 + \frac{1}{2}\widetilde{Q}_3.$$
(35)

Following the same procedure for (25b), we have that

$$0 = \widehat{W}^{\mathsf{T}} \widehat{E} \widehat{V} + \widetilde{W}^{\mathsf{T}} E \widetilde{V}.$$

Noting that  $LL^{\mathsf{T}} = \begin{bmatrix} 1 & 1/2 \\ 1/2 & 1/3 \end{bmatrix}$ , from (25c) it follows that

$$\begin{split} \left[0 \ 0\right] &= \int_0^1 \int_0^1 \left[1 \ \mathsf{p}_1\right] \left( \left(\widehat{Q}_1 + \mathsf{p}_2 \widehat{Q}_2 + \mathsf{p}_2^2 \widehat{Q}_3\right)^\mathsf{T} \left(\widehat{B}_1 + \mathsf{p}_1 \widehat{B}_2\right) \right. \\ &\qquad \qquad + \left. \left(\widetilde{Q}_1 + \mathsf{p}_2 \widetilde{Q}_2 + \mathsf{p}_2^2 \widetilde{Q}_3\right)^\mathsf{T} \left(B_1 + \mathsf{p}_1 B_2\right) \right) \mathrm{d} \mathsf{p}_1 \, \mathrm{d} \mathsf{p}_2 \\ &= \left[ \widehat{W}^\mathsf{T} \left(\widehat{B}_1 + \frac{1}{2} \widehat{B}_2\right) + \widetilde{W}^\mathsf{T} \left(B_1 + \frac{1}{2} B_2\right) \ \middle| \ \widehat{W}^\mathsf{T} \left(\frac{1}{2} \widehat{B}_1 + \frac{1}{3} \widehat{B}_2\right) + \widetilde{W}^\mathsf{T} \left(\frac{1}{2} B_1 + \frac{1}{3} B_2\right) \right] \\ &= \widehat{W}^\mathsf{T} \left[ \widehat{B}_1 \quad \widehat{B}_2 \right] L L^\mathsf{T} + \widetilde{W}^\mathsf{T} \left[B_1 \quad B_2\right] L L^\mathsf{T}. \end{split}$$

Multiplying the equation above on the right by the inverse of  $L^{\mathsf{T}}$ , we obtain

$$0 = \widehat{W}^{\mathsf{T}} \widehat{B}_L + \widetilde{W}^{\mathsf{T}} B_L$$

Analogously, (25d) simplifies to

$$0 = \widehat{C}_T \widehat{V} - C_T \widetilde{V}.$$

It remains to show that  $\widehat{P}_L$ ,  $\widetilde{P}_L$ ,  $\widehat{Q}_L$ ,  $\widehat{Q}_L$  in (31) are equal, respectively, to  $\widehat{V}$ ,  $\widehat{V}$ ,  $\widehat{W}$ ,  $\widehat{W}$  in (35). We show this only for  $\widetilde{V}$ , as it follows similarly for the remaining matrices. By the following weighted sum (33a) +  $\frac{1}{2}$ (33b) +  $\frac{1}{3}$ (33c), we obtain

$$0 = A\widetilde{V}\widehat{E}^{\mathsf{T}} + E\widetilde{V}\widehat{A}^{\mathsf{T}} + B_1\widehat{B}_1^{\mathsf{T}} + \frac{1}{2} \Big( B_1\widehat{B}_2^{\mathsf{T}} + B_2\widehat{B}_1^{\mathsf{T}} \Big) + \frac{1}{3}B_2\widehat{B}_2^{\mathsf{T}}$$
$$= A\widetilde{V}\widehat{E}^{\mathsf{T}} + E\widetilde{V}\widehat{A}^{\mathsf{T}} + \begin{bmatrix} B_1 & B_2 \end{bmatrix} LL^{\mathsf{T}} \begin{bmatrix} \widehat{B}_1 & \widehat{B}_2 \end{bmatrix}^{\mathsf{T}}$$
$$= A\widetilde{V}\widehat{E}^{\mathsf{T}} + E\widetilde{V}\widehat{A}^{\mathsf{T}} + B_L\widehat{B}_L^{\mathsf{T}}.$$

## 4.2 Unit-disk optimality results of Grimm

Let  $\mathbb{C}_+$  denote the open right half-plane and  $\mathbb{D} = \{z \in \mathbb{C} : |z| \leq 1\}$  the complex unit disk. Grimm [13, Chapter 3] considered the following variant of the  $\mathcal{H}_2 \otimes \mathcal{L}_2$  norm for single-input, single-output systems:

$$\|G\|_{\mathcal{H}_2 \otimes \mathcal{L}_2} := \left(\frac{1}{4\pi^2} \int_{-\infty}^{\infty} \int_{0}^{2\pi} |G(\mathbf{i}\omega, e^{\mathbf{i}\theta})|^2 d\theta d\omega\right)^{1/2},$$

where function  $G: \mathbb{C} \times \mathbb{C} \to \mathbb{C}$  is analytic on  $\mathbb{C}_+ \times \mathbb{D}$ . The FOM is assumed to have the form as in (1), while Grimm additionally assumes that E, A, B, C are analytic. The aim is to find an optimal ROM whose transfer function is of the form

$$\widehat{H}(s;\mathbf{p}) = \sum_{i=1}^{r_s} \sum_{j=1}^{r_p} \frac{\phi_{i,j}}{(s-\lambda_i)(\mathbf{p}-\pi_j)},$$

where  $\phi_{i,j} \in \mathbb{C}$ ,  $\lambda_i \in \mathbb{C}$  with  $\text{Re}(\lambda_i) < 0$ , and  $\pi_j \in \mathbb{C}$  with  $|\pi_j| > 0$ , for  $i \in [r_s]$  and  $j \in [r_p]$ . The interpolatory FONC were derived in [13, Theorem 3.3.4] and an optimization-based approach for satisfying them was proposed.

Note that one possible state-space realization of  $\widehat{H}$  is

$$\begin{split} & \dot{\widehat{x}}(t;\mathbf{p}) = \begin{bmatrix} \lambda_1 & & \\ & \ddots & \\ & \lambda_{r_s} \end{bmatrix} \widehat{x}(t;\mathbf{p}) + \begin{bmatrix} 1 \\ \vdots \\ i \end{bmatrix} u(t), \\ & \widehat{y}(t;\mathbf{p}) = \sum_{i=1}^{r_p} \frac{1}{\mathbf{p} - \pi_j} \begin{bmatrix} \phi_{1,j} & \cdots & \phi_{r_s,j} \end{bmatrix} \widehat{x}(t;\mathbf{p}). \end{split}$$

Defining the matrix  $\Phi = [\phi_{i,j}]_{i \in [r_s], j \in [r_p]}$ ,  $\widehat{C}$  can be written in parameter-separable form  $\widehat{C}(\mathsf{p}) = \widehat{C}(\mathsf{p})$  $\sum_{j=1}^{r_p} \frac{1}{\mathsf{p}-\pi_j} (\Phi e_j)^\mathsf{T}$ , with functions  $\widehat{c}_j(\mathsf{p}) = \frac{1}{\mathsf{p}-\pi_j}$  and reduced-order matrices  $\widehat{C}_j = (\Phi e_j)^\mathsf{T}$  for  $j \in [r_p]$ . The main similarity to our setting is the usage of parameter-separable forms. However, there are appreciable differences. The first is that here the scalar parameter is varying in D, while in our setting, the parameters live in a subset of  $\mathbb{R}^d$ . The second is that only  $\widehat{C}$  varies with the parameter, which is a limitation compared to also allowing  $\widehat{E}$ ,  $\widehat{A}$  and  $\widehat{B}$  to depend on the parameter. Finally, here the scalar functions  $\hat{c}_i$  are not fixed in advance and the scalars  $\pi_i$  are optimized, but our approach could be directly extended to additionally allow optimization variables in the scalar functions.

## 4.3 Discretized optimality results of Petersson

A discretized, frequency-weighted  $\mathcal{H}_2 \otimes \mathcal{L}_2$ -like objective function is considered in [22, Chapter 5], i.e.,

$$\mathcal{J}_{\mathrm{d}}(\widehat{\Sigma}_{\mathcal{P}}) := \sum_{i=1}^{n_p} \left\| W_i^{\mathrm{out}} \left( H(\cdot; \mathsf{p}^{(i)}) - \widehat{H}(\cdot; \mathsf{p}^{(i)}) \right) W_i^{\mathrm{in}} \right\|_{\mathcal{H}_2}^2, \tag{36}$$

for fixed  $p^{(1)}, p^{(2)}, \dots, p^{(n_p)} \in \mathcal{P}$ , where  $W_i^{\text{in}}$  and  $W_i^{\text{out}}$  are asymptotically stable transfer functions of input and output weights with respect to the parameter  $p^{(i)}$  for  $i \in [n_p]$ . Petersson uses similar parameter-separable forms for  $\widehat{A}, \widehat{B}, \widehat{C}$  as we do, except with fixed  $\widehat{E}(p) = I$ . For the function in (36), Petersson derived Wilson-type FONC and also proposed an optimization-based approach to satisfy them.

To compare this approach to ours, note that the Lebesgue measure in the definition  $\mathcal{H}_2 \otimes \mathcal{L}_2$ norm (10) can be replaced with any nontrivial, finite, Borel measure  $\mu$  over  $\mathcal{P}$ , and our results will still hold. In fact, the only necessary change is using the measure theory version of the Leibniz rule [12, Theorem 2.27] in the proof of Theorem 3.1. Now letting the measure  $\mu$  be the sum of Dirac measures  $\delta_{p^{(i)}}$ , i.e.,  $\mu(S) = |S \cap \{p^{(1)}, p^{(2)}, \dots, p^{(n_p)}\}|$  for every subset S of  $\mathcal{P}$ , we recover the non-weighted discretized  $\mathcal{H}_2 \otimes \mathcal{L}_2$  norm as in (36). Therefore, after including weights, it can be seen that our work is a generalization of Petersson's results. Furthermore, for the setting where  $\mu$  is a Lebesgue measure, the disadvantage of using (36) is that the parameter values  $p^{(1)}, p^{(2)}, \dots, p^{(n_p)}$ have to be chosen in advance, i.e., fixed. In contrast, the adaptive quadrature used in our approach provides guarantees on the numerical accuracy, unlike parameter values chosen a priori.

## 5 A TSIA-based algorithm for parametric MOR

For non-parametric systems, TSIA is the fixed-point iteration given by

$$\begin{split} \widehat{E}_{k+1} &= -\widehat{Q}_k^{-\mathsf{T}} \widetilde{Q}_k^{\mathsf{T}} E \widetilde{P}_k \widehat{P}_k^{-1}, \quad \widehat{A}_{k+1} = -\widehat{Q}_k^{-\mathsf{T}} \widetilde{Q}_k^{\mathsf{T}} A \widetilde{P}_k \widehat{P}_k^{-1}, \\ \widehat{B}_{k+1} &= -\widehat{Q}_k^{-\mathsf{T}} \widetilde{Q}_k^{\mathsf{T}} B, \qquad \widehat{C}_{k+1} = C \widetilde{P}_k \widehat{P}_k^{-1}, \end{split}$$

based on the Wilson conditions (8), where  $\widetilde{P}_k$ ,  $\widetilde{Q}_k$ ,  $\widehat{P}_k$ ,  $\widehat{Q}_k$  are Gramian blocks coming from  $(\widehat{E}_k, \widehat{A}_k, \widehat{B}_k, \widehat{C}_k)$ . Furthermore, the inverses of  $\widehat{P}_k$  and  $\widehat{Q}_k$  are in fact not even needed in TSIA, since

$$\widehat{E}_{k+1} = \widetilde{Q}_k^\mathsf{T} E \widetilde{P}_k, \quad \widehat{A}_{k+1} = \widetilde{Q}_k^\mathsf{T} A \widetilde{P}_k, \quad \widehat{B}_{k+1} = \widetilde{Q}_k^\mathsf{T} B, \quad \widehat{C}_{k+1} = C \widetilde{P}_k,$$

defines an equivalent ROM (also,  $\widetilde{P}_k$  and  $\widetilde{Q}_k$  can be first orthonormalized).

When we began this work on  $\mathcal{H}_2 \otimes \mathcal{L}_2$  MOR, we originally considered extending TSIA using the parametric FONC (25). However, limitations with this approach quickly became apparent. First, this does not permit all parameter-separable forms in the ROM. For instance, inserting  $\widehat{A}$  from (12) into (25a) yields

$$0 = \int_{\mathcal{P}} \widehat{e}_i(\mathsf{p}) \left( \widehat{Q}(\mathsf{p})^\mathsf{T} \sum_{j=1}^{q_{\widehat{A}}} \left( \widehat{a}_j(\mathsf{p}) \widehat{A}_j \right) \widehat{P}(\mathsf{p}) + \widetilde{Q}(\mathsf{p})^\mathsf{T} A(\mathsf{p}) \widetilde{P}(\mathsf{p}) \right) d\mathsf{p}, \qquad i \in [q_{\widehat{E}}],$$

which is a linear system of  $q_{\widehat{E}}r^2$  equations and  $q_{\widehat{A}}r^2$  unknowns (the entries of the matrices  $\widehat{A}_j$ ). Therefore, to have a unique solution,  $q_{\widehat{A}}$  and  $q_{\widehat{E}}$  must be equal. Second, even for the simple example

$$\begin{split} q_{\widehat{A}} &= q_{\widehat{E}} = 2, & \widehat{a}_1(\mathsf{p}) = \widehat{e}_1(\mathsf{p}) = \widehat{b}_1(\mathsf{p}) = \widehat{c}_1(\mathsf{p}) = 1, \\ q_{\widehat{B}} &= q_{\widehat{C}} = 1, & \widehat{a}_2(\mathsf{p}) = \widehat{e}_2(\mathsf{p}) = \mathsf{p}, \end{split}$$

we observed that our parametric TSIA algorithm would not converge in practice, and in particular, would not preserve stability. A key difference in this parametric setting is that it does not seem possible to eliminate  $\hat{P}_k(\mathbf{p})$  and  $\hat{Q}_k(\mathbf{p})$  (unlike in non-parametric TSIA). This can be problematic since inverses of matrices involving  $\hat{P}_k$  and  $\hat{Q}_k$  are needed to obtain the next iterate, and these matrices may be ill-conditioned for  $\mathbf{p} \in \mathcal{P}$ . In contrast, our new approach, which we are about to describe, can use any parameter-separable form for the ROM without ever needing such inverses.

# 6 An optimization-based approach for parametric MOR

The objective function in (13) is smooth, and via Theorem 3.1, we have derived its gradient with respect to the reduced-order matrices given in (12). Before we take advantage of these properties for our new optimization-based algorithm for  $\mathcal{H}_2 \otimes \mathcal{L}_2$ -optimal MOR, we first address the stability constraint in (13).

## 6.1 Evaluating the stability constraint

For a given  $p \in \mathcal{P}$ , it is easy to check whether or not  $\alpha(\widehat{A}(p), \widehat{E}(p)) < 0$  holds, but checking whether a ROM is asymptotically stable over all  $p \in \mathcal{P}$  is more difficult. We propose testing whether  $\max_{p \in \mathcal{P}} \alpha(\widehat{A}(p), \widehat{E}(p)) < 0$  holds via Chebfun [11], which "is an open-source package for computing with functions to about 15-digit accuracy." By having Chebfun build a high-fidelity interpolant approximation (called a chebfun) to  $\alpha(\widehat{A}(p), \widehat{E}(p))$  on domain  $\mathcal{P}$ , we can then easily and efficiently obtain its global maximizer(s). This allows us to reliably ascertain stability over  $\mathcal{P}$ .

<sup>&</sup>lt;sup>1</sup>This quote is taken from http://www.chebfun.org, where Chebfun can be downloaded.

## 6.2 Our optimization-based MOR algorithm

Since the objective function in (13) is smooth and we can compute its gradient, we can consider applying fast optimization techniques, e.g., BFGS, in order to compute locally optimal ROMs. Since the number of optimization variables for a ROM given by (12) is  $N = (q_{\widehat{E}} + q_{\widehat{A}})r^2 + (q_{\widehat{B}}m + q_{\widehat{C}}p)r$  and BFGS does  $\mathcal{O}(N^2)$  work per iteration and uses  $\mathcal{O}(N^2)$  memory, a BFGS-based MOR algorithm would require  $\mathcal{O}(r^4)$  work and memory, which is reasonable as  $r \ll n$  is not only typical but desired. Moreover, under sufficient smoothness conditions, BFGS also has superlinear local convergence. Thus, we expect the cost of such an optimization-based algorithm actually to be dominated by the costs just to evaluate the objective function  $\mathcal J$  and its gradient at different ROMs encountered by the algorithm. While directly evaluating  $\mathcal J$  and  $\nabla \mathcal J$  would be expensive, we now explain how these computations can be made much cheaper.

Note that the objective function given in (13) can be written as

$$\mathcal{J}(\widehat{\Sigma}_{\mathcal{P}}) = \int_{\mathcal{P}} \operatorname{tr}\left(C(\mathsf{p})P(\mathsf{p})C(\mathsf{p})^{\mathsf{T}} + \widehat{C}(\mathsf{p})\widehat{P}(\mathsf{p})\widehat{C}(\mathsf{p})^{\mathsf{T}} - 2C(\mathsf{p})\widetilde{P}(\mathsf{p})\widehat{C}(\mathsf{p})^{\mathsf{T}}\right) d\mathsf{p}$$

$$= \|H\|_{\mathcal{H}_{2}\otimes\mathcal{L}_{2}}^{2} + \int_{\mathcal{P}} \operatorname{tr}\left(\widehat{C}(\mathsf{p})\widehat{P}(\mathsf{p})\widehat{C}(\mathsf{p})^{\mathsf{T}} - 2C(\mathsf{p})\widetilde{P}(\mathsf{p})\widehat{C}(\mathsf{p})^{\mathsf{T}}\right) d\mathsf{p} \tag{37}$$

Since the first term in (37), i.e., the squared  $\mathcal{H}_2 \otimes \mathcal{L}_2$  norm of the FOM, is actually a constant, for the purpose of finding minimizers, we can replace  $\mathcal{J}$  in (13) with

$$\mathcal{J}_{s}(\widehat{\Sigma}_{\mathcal{P}}) = \int_{\mathcal{P}} \operatorname{tr}(\widehat{C}(\mathsf{p})\widehat{P}(\mathsf{p})\widehat{C}(\mathsf{p})^{\mathsf{T}} - 2C(\mathsf{p})\widetilde{P}(\mathsf{p})\widehat{C}(\mathsf{p})^{\mathsf{T}}) d\mathsf{p}, \tag{38}$$

noting that  $\nabla \mathcal{J}_s = \nabla \mathcal{J}$  of course still holds. For a given  $p \in \mathcal{P}$ ,  $\widetilde{P}(p)$  in (38) can be obtained in  $\mathcal{O}(rS+nr^2)$  work by solving the  $n\times r$  Sylvester equation (16b), where solving a shifted linear system (sE(p) - A(p))x = b is  $\mathcal{O}(S)$  work [6]. Meanwhile, via solving the  $r \times r$  Lyapunov equation (16c), we obtain  $\widehat{P}(p)$  in (38) in just  $\mathcal{O}(r^3)$  work [2]. In contrast, if we were to evaluate (37), we would need P(p), which would involve solving a large  $n \times n$  Lyapunov equation (16a), and thus be much more expensive to compute. While (38) and its gradient requires evaluating an integral for each entry in the ROM matrices in (12), these integrals can be bundled together in a single call to integral in MATLAB such that the integrals make use of the same quadrature points. This is a crucial implementation detail as otherwise  $\widetilde{P}(p)$  and  $\widehat{P}(p)$  would likely be recomputed many times over for the same values of  $p \in \mathcal{P}$  during integration. Finally, note that we do not even evaluate (38) (and its gradient) if we detect that  $\max_{p\in\mathcal{P}} \alpha(\widehat{A}(p), \widehat{E}(p)) \geq 0$ ; in this case, we simply return  $\mathcal{J}_s = \infty$  and any vector for  $\nabla \mathcal{J}_s$ . This serves two purposes. First, it ensures that the optimization solver will only accept asymptotically stable ROMs on each iteration, thus guaranteeing we always compute feasible (stable) solutions to (37). This also means that we do not need to use a solver for constrained optimization to find solutions to (37), i.e., an unconstrained optimization solver suffices. Second, we also avoid the cost of evaluating  $\mathcal{J}_s$  and  $\nabla \mathcal{J}_s$  at any unstable ROMs encountered, e.g., within line searches.

#### 6.3 Additional implementation and termination details

Although our optimization-based algorithm ensures that it will only ever accept asymptotically stable ROMs on each iteration, it still must be initialized at an asymptotically stable ROM. But this is generally easy to satisfy via a variety of techniques. For example, assuming that  $\hat{e}_1$  and  $\hat{a}_1$  are positive over  $\mathcal{P}$ , we can easily construct an invertible  $\hat{E}_1$  and  $\hat{A}_1$  such that  $\alpha(\hat{A}_1, \hat{E}_1) < 0$  and then set  $\hat{E}_i = 0$  and  $\hat{A}_j = 0$  for  $i, j \geq 2$ . Alternatively, starting with an arbitrary ROM with matrix-valued functions of the form as in (12) but not in  $\mathcal{R}$ , one can use nonsmooth optimization techniques to minimize  $\max_{\mathbf{p} \in \mathcal{P}} \alpha(\hat{A}(\mathbf{p}), \hat{E}(\mathbf{p}))$  until it is negative and then use the resulting ROM to initialize our method. Even though our method ensures stable ROMs at every iteration, encountering nearly unstable ROMs may cause numerical issues when computing  $\tilde{P}(\mathbf{p})$  and  $\hat{P}(\mathbf{p})$ , e.g., these computed matrices may contain inf or NaN entries or lyap may throw an error when solving (16c). However, these scenarios are trivially handled by detecting these cases and once again just returning  $\infty$  for

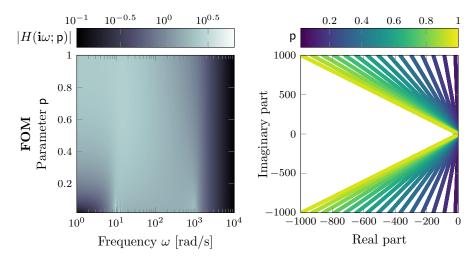

Figure 1: Frequency response magnitude  $|H(\mathbf{i}\omega; \mathbf{p})|$  and system poles of Example 1.

the value of  $\mathcal{J}_s$ . Finally, we propose the following tolerance criterion to determine when to halt optimization:

$$\frac{\|\widehat{H}^{i} - \widehat{H}^{i-1}\|_{\mathcal{H}_2 \otimes \mathcal{L}_2}}{\|\widehat{H}^{i-1}\|_{\mathcal{H}_2 \otimes \mathcal{L}_2}} < \text{tol}, \tag{39}$$

where  $\widehat{H}^i$  denotes the transfer function of a ROM (2) in the *i*th iteration of optimization. Note that (39) is cheap to compute (it uses only ROM matrices) and measures the relative change in performance between consecutive ROMs during optimization. Thus, when the ROMs are not changing significantly, this quantity will be small.

## 7 Numerical experiments

All experiments were done in MATLAB R2019b on a computer with two Intel Xeon Silver 4110 CPUs (8 cores per CPU) and 192 GB of RAM. Running times were measured using tic and toc. We implemented our new algorithm using GRANSO: GRadient-based Algorithm for Non-Smooth Optimization.<sup>2</sup> We used GRANSO because (a) it supports custom stopping criteria, which we used to implement (39), and (b) when no constraints are given explicitly (per our implementation description in Section 6), GRANSO does BFGS (for constrained problems, GRANSO uses the BFGS-SQP algorithm of [10]). We used GRANSO v1.6.4 with its default parameters, except that we set opts.maxit = 250 and opts.opt\_tol = 0. We set the latter parameter to zero since we only want to halt optimization of the ROM once (39) is satisfied; for this custom stopping condition, we used tol = 10<sup>-5</sup>. Our software, used to compute all results reported here, is open source.<sup>3</sup>

$$E\dot{x}(t;\mathbf{p}) = (A_1 + \mathbf{p}A_2)x(t;\mathbf{p}) + Bu(t),$$
  

$$y(t;\mathbf{p}) = Cx(t;\mathbf{p}).$$
(40)

This choice allowed us to use projection-based methods for both initialization and as a comparison to our optimization-based approach. We refer to this alternative as pIRKA ("piecewise IRKA"), as it is based on the piecewise  $\mathcal{H}_2$ -optimal interpolatory parametric MOR method [3, Algorithm 5.1]; pIRKA consists of:

1. choosing  $p_s$  linearly-spaced parameter values  $p^{(1)}, \ldots, p^{(p_s)} \in \mathcal{P}$ ,

<sup>3</sup>DOI: 10.5281/zenodo.3663490

<sup>&</sup>lt;sup>2</sup>Available at http://www.timmitchell.com/software/GRANSO/.

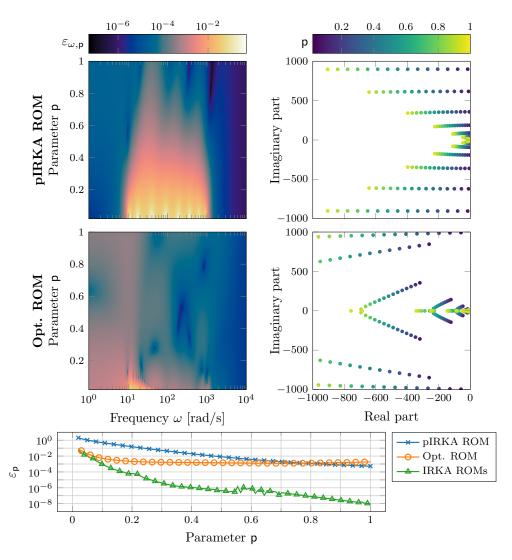

Figure 2: Example 1 ROM performance. Scaled frequency response error  $\varepsilon_{\omega,p}$  and poles for the pIRKA ROM (top row), the same for our optimization-derived ROM (middle row), and scaled  $\mathcal{H}_2$  error  $\varepsilon_p$  for the pIRKA ROM, our optimized-derived ROM, and various pointwise non-parametric IRKA-derived ROMs (bottom).

- 2. reducing local non-parametric models  $H(\cdot; \mathsf{p}^{(i)})$  using IRKA to obtain local basis matrices  $V^{(i)}, W^{(i)} \in \mathbb{R}^{n \times r_s}$  for some  $r_s < n$ ,
- 3. choosing a global basis matrix V as the first  $r \leq 2p_s r_s$  left singular vectors of

$$\begin{bmatrix} V^{(1)} & \cdots & V^{(p_s)} & W^{(1)} & \cdots & W^{(p_s)} \end{bmatrix},$$

4. projecting full-order matrices

$$\hat{E} = V^\mathsf{T} E V, \quad \hat{A}_1 = V^\mathsf{T} A_1 V, \quad \hat{A}_2 = V^\mathsf{T} A_2 V, \quad \hat{B} = V^\mathsf{T} B, \quad \hat{C} = C V.$$

In step 2, we used mess\_tangential\_irka from the Matrix Equation Sparse Solver (M-M.E.S.S.) library [23] with the following settings in the opts.irka structure:  $\mathbf{r} = r_s$ , maxiter = 100,  $h2\_tol = shift\_tol = 10^{-6}$ , and flipeig = 0. We used a one-sided projection in step 4 because for our examples here, which are all uniformly strictly dissipative (for all  $\mathbf{p} \in \mathcal{P}$ ,  $A(\mathbf{p}) + A(\mathbf{p})^T$  and  $E(\mathbf{p})$  are, respectively, negative definite and positive definite), it guarantees asymptotic stability of the ROM for all parameters.

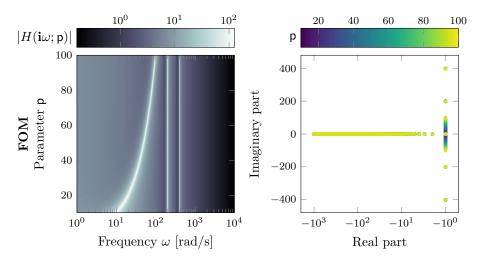

Figure 3: Frequency response magnitude  $|H(i\omega; p)|$  and system poles of Example 2.

To compare accuracies, for each ROM, we computed the  $\mathcal{H}_2 \otimes \mathcal{L}_2$  error once using (14) and mess\_lradi from M-M.E.S.S., so that the large Lyapunov equation in (15a) or (15b) could be efficiently solved. For conciseness, we introduce:

$$\varepsilon = \frac{\left\|H - \widehat{H}\right\|_{\mathcal{H}_2 \otimes \mathcal{L}_2}}{\|H\|_{\mathcal{H}_2 \otimes \mathcal{L}_2}}, \ \varepsilon_{\mathsf{p}} = \frac{\left\|H(\cdot; \mathsf{p}) - \widehat{H}(\cdot; \mathsf{p})\right\|_{\mathcal{H}_2}}{\|H\|_{\mathcal{H}_2 \otimes \mathcal{L}_2}}, \ \varepsilon_{\omega, \mathsf{p}} = \frac{\left\|H(\mathbf{i}\omega; \mathsf{p}) - \widehat{H}(\mathbf{i}\omega; \mathsf{p})\right\|_{\mathcal{F}}}{\|H\|_{\mathcal{H}_2 \otimes \mathcal{L}_2}}.$$

In order,  $\varepsilon$  is the relative  $\mathcal{H}_2 \otimes \mathcal{L}_2$  error,  $\varepsilon_{\mathsf{p}}$  is the  $\mathcal{H}_2$  error for a particular parameter value  $\mathsf{p}$  relative to the  $\mathcal{H}_2 \otimes \mathcal{L}_2$  norm of the original system, while finally,  $\varepsilon_{\omega,\mathsf{p}}$  is the transfer function value error for a particular frequency  $\omega$  and parameter value  $\mathsf{p}$  relative to the  $\mathcal{H}_2 \otimes \mathcal{L}_2$  norm of the original system.

#### 7.1 Example 1: A synthetic parametric model

Our first example is the synthetic parametric model [25], where we used n = 1000 for the order of the FOM and  $\mathcal{P} = [0.02, 1]$  as the parameter set. From Fig. 1, we see that the system poles become closer to the imaginary axis as p decreases. For computing ROMs, we chose r = 16 (so 800 optimization variables) and used  $p_s = 4$  and  $r_s = 4$  for pIRKA.

The initial ROM computed by pIRKA resulted in a relative error of  $\varepsilon = 0.3145$ . Meanwhile, optimizing the ROM using GRANSO took 250 iterations (17 minutes), reducing the relative error to  $\varepsilon = 8.395 \times 10^{-3}$ . In other words, our new approach produced a ROM whose  $\mathcal{H}_2 \otimes \mathcal{L}_2$  error is about 37 times better than the one obtained by pIRKA alone. Figure 2 shows the behavior of ROMs from pIRKA and GRANSO. On the top left, bright peaks can be seen for the pIRKA, i.e., regions where the ROM does not approximate the FOM well. On the middle right, the errors overall are more homogeneous and smaller. Comparing ROM poles (top right and middle right), we see that poles for the pIRKA ROM and FOM move horizontally in a similar fashion with respect to p, while GRANSO found a ROM with a more complex parameter dependency of the poles. The error improvement is also depicted in the bottom graph, where we observe that optimization produced a ROM that is better for most parameter values in  $\mathcal{P}$  and up to two orders of magnitude for some. To get a sense for how close our ROM computed by GRANSO is to optimal unstructured ROMs (where  $\hat{E}, \hat{A}, \hat{B}, \hat{C}$  are arbitrary matrices), the figure also shows the results from running IRKA for individual parameter values. Note that this is only an indication for the lower bound, since IRKA can not be guaranteed to find a global minimum (the jumps in the curve confirm this). We see that GRANSO's ROM appears to be close to the optimal ROMs for small parameter values, while the error flattens for larger ones.

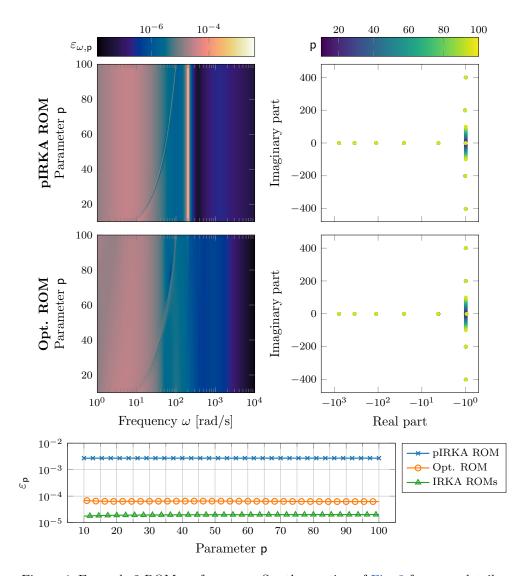

Figure 4: Example 2 ROM performance. See the caption of Fig. 2 for more details.

#### 7.2 Example 2: A parametric version of Penzl's FOM

We now consider the parameterized version of the Penzl FOM [21] used in [16], where n = 1006 and  $\mathcal{P} = [10, 100]$ . As illustrated in Fig. 3, changing the parameter moves one of the complex conjugate pairs of poles. Here we used r = 12 (so 456 optimization variables) and  $p_s = 3$  and  $r_s = 4$  for pIRKA.

For this FOM, pIRKA produced a ROM with a relative error of  $\varepsilon = 2.574 \times 10^{-2}$ . In contrast, our optimization-based algorithm reduced that error to  $\varepsilon = 6.051 \times 10^{-4}$ , i.e., about 43 times better, which took 70 optimization iterations (6.6 minutes). From Fig. 4, it seems that the major factor determining the quality of the ROMs was how well the middle peak was captured. We also see that there is more than a 1.5 orders of magnitude improvement in GRANSO's ROM for all parameter values. The errors for the unstructured ROMs are better but by less than an order of magnitude.

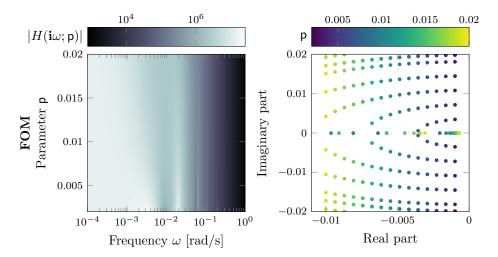

Figure 5: Frequency response magnitude  $|H(\mathbf{i}\omega; \mathbf{p})|$  and a subset of the system poles (ones near the origin) of Example 3.

## 7.3 Example 3: A parametric version of the triple chain example

Our last example is a parametric version of the triple chain example [26]

$$\mathcal{M}\ddot{x}(t;\mathbf{p}) + \mathcal{D}(\mathbf{p})\dot{x}(t;\mathbf{p}) + \mathcal{K}x(t;\mathbf{p}) = \mathcal{B}u(t),$$

$$y(t;\mathbf{p}) = \mathcal{C}x(t;\mathbf{p}),$$
(41)

a second-order system with  $\mathcal{M}, \mathcal{D}(\mathsf{p}), \mathcal{K} \in \mathbb{R}^{\widetilde{n} \times \widetilde{n}}, \ \mathcal{B}, \mathcal{C}^\mathsf{T} \in \mathbb{R}^{\widetilde{n} \times 1}$ , and  $\widetilde{n} = 1501$ . The damping matrix is  $\mathcal{D} = \alpha \mathcal{M} + \beta \mathcal{K}$  with scalars  $\alpha, \beta > 0$ , so by choosing  $\mathsf{p} = \alpha = \beta$ , we have the parameter dependency  $\mathcal{D}(\mathsf{p}) = \mathsf{p}(\mathcal{M} + \mathcal{K})$ . Figure 5 shows the frequency response of the system and its poles near the origin; as expected, the poles move closer to the imaginary axis as damping is decreased. Using the procedure described in [20], the second-order system (41) can be transformed into a strictly dissipative first-order realization of the form (40) with order  $n = 2\widetilde{n} = 3002$  and matrices

$$E = \left[ \begin{smallmatrix} \mathcal{K} & \gamma \mathcal{M} \\ \gamma \mathcal{M} & \mathcal{M} \end{smallmatrix} \right], \ A_1 = \left[ \begin{smallmatrix} -\gamma \mathcal{K} & \mathcal{K} \\ -\mathcal{K} & \gamma \mathcal{M} \end{smallmatrix} \right], \ A_2 = \left[ \begin{smallmatrix} 0 & -\gamma (\mathcal{M} + \mathcal{K}) \\ 0 & -(\mathcal{M} + \mathcal{K}) \end{smallmatrix} \right], \ B = \left[ \begin{smallmatrix} \gamma \mathcal{B} \\ \mathcal{B} \end{smallmatrix} \right], \ C = [\, \mathcal{C} \,\, \mathbf{0} \,\, ],$$

where  $0 < \gamma < \min_{\mathbf{p} \in \mathcal{P}} \Lambda(\mathcal{D}(\mathbf{p}), \mathcal{M} + \frac{1}{4}\mathcal{D}(\mathbf{p})\mathcal{K}^{-1}\mathcal{D}(\mathbf{p}))$ . For our experiment, we used  $\mathcal{P} = [2 \times 10^{-3}, 2 \times 10^{-2}]$  and  $\gamma = \frac{1}{2} \min_{\mathbf{p} \in \mathcal{P}} \Lambda(\mathcal{D}(\mathbf{p}), \mathcal{M} + \frac{1}{4}\mathcal{D}(\mathbf{p})\mathcal{K}^{-1}\mathcal{D}(\mathbf{p}))$ , where  $\gamma$  was computed using Chebfun. Finally, we used r = 4 (so 56 optimization variables) and  $r_s = 2$  and r = 4 for pIRKA. Note that the transformation to a strictly dissipative form is only needed for pIRKA to guarantee an asymptotically stable ROM. The optimization procedure can work with other first-order realizations of the FOM.

Here, pIRKA produced a ROM with relative error  $\varepsilon = 5.267 \times 10^{-2}$ . Our optimization-based algorithm reduced this error to  $\varepsilon = 2.506 \times 10^{-2}$ , i.e., about 2.1 times better, and took 225 iterations (58 minutes). From Fig. 6, we see most of the reduction in error for lower frequencies. We also see that GRANSO's ROM is very close to the optimal unstructured model for most of the parameter values.

# 8 Concluding remarks

In our new MOR method using gradients of the  $\mathcal{H}_2 \otimes \mathcal{L}_2$  error, solving the numerous sparse-dense Sylvester equations is the vast majority of the overall cost. As such, faster methods for parametric matrix equations could make our method even more efficient, and so, leveraging reduced basis approaches or tensor techniques, e.g., [17, 24], are promising research directions. Moreover, it could be interesting to investigate the numerical stability issues in parametric TSIA or alternative ROM representations that might eliminate the need for inverses.
