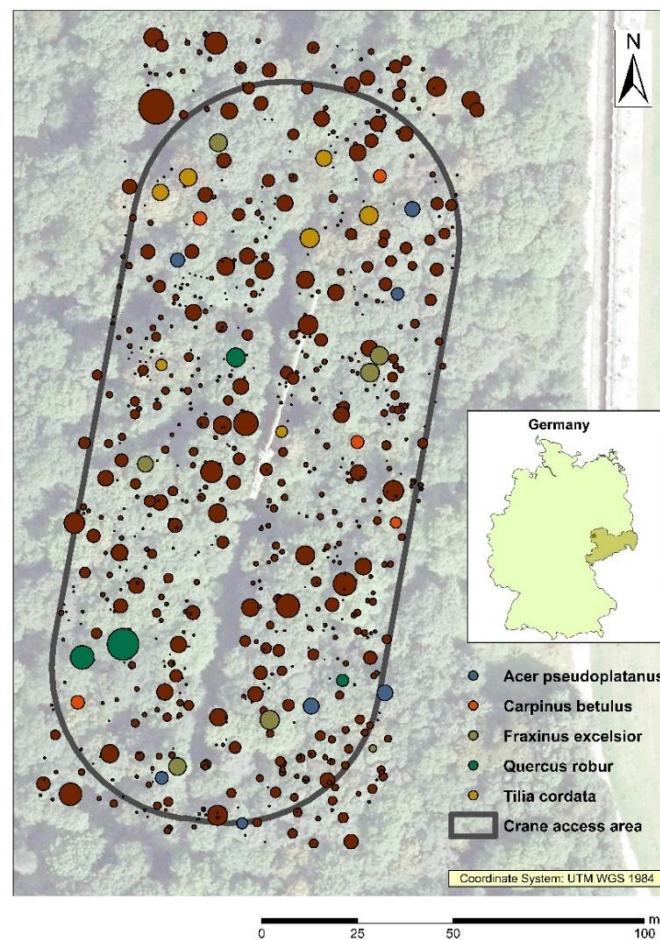

Figure S1. Leipzig canopy crane facility (LCC) and locations of the tree individuals selected for our study; species identity is color-coded; tree individuals not being selected for our study appear in brown.

Figure S2. Images obtained in *C. betulus* used to predict canopy cover. A clear trend towards a lower canopy cover becomes visible when comparing images from the moist period in May / June to the dry period in August / September.

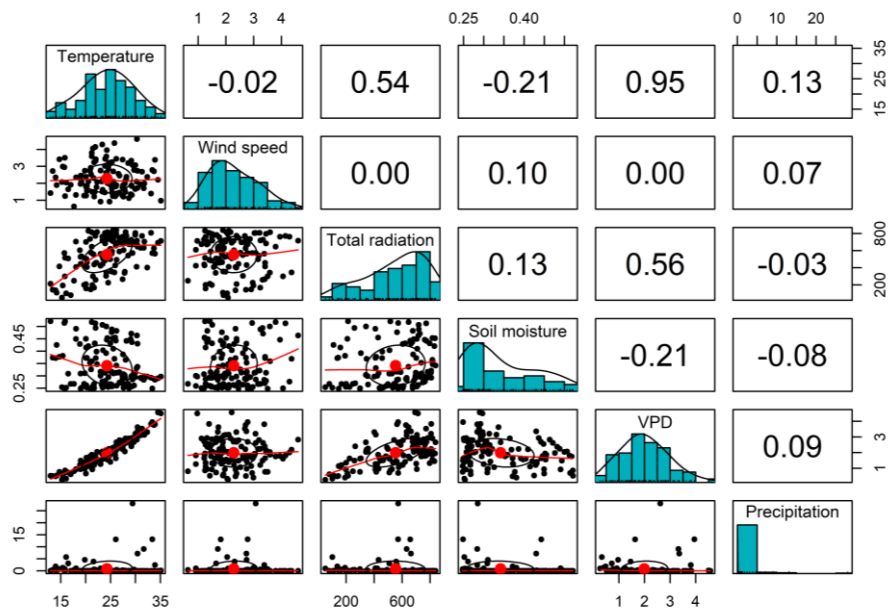

Figure S3. Bivariate relationships (Pearson correlation) between environmental characteristics measured during our study period (May 15th to September 15th in 2018).

Table S4. SEM results testing for the effects of the biotic and environmental template on between species variability in canopy temperatures (T_{var}) at the top of the canopy under dry and moist conditions; Std. Estimate = standardized coefficient, df = degrees of freedom, Crit. = critical value ratio, p – value = p – value; significant relationships are highlighted in bold.
