## Abstract

TikTok is a relatively novel and widely popular media platform. In response to its expanding user base and cultural impact, researchers are turning to study the platform; however, TikTok, like many social media platforms, restricts external access to data. Prior works have acquired data from scraping the platform, user self-reports, and from accounts created by researchers for the study’s purpose. Existing techniques, while yielding important insights, contain limitations for gathering large-scale quantitative insights on how real TikTok users behave on the platform. We bridge this research gap by implementing a data donation system to collect TikTok data. Our system leverages users’ right to access their data enabled by the EU’s GDPR regulation. We recruit 347 TikTok users, ask them to request their data from TikTok, and then use our system to customize, anonymize, and donate their data. We collect 4.9M videos viewed 9.2M times by our participants – and associated engagement metrics – to analyze how people consume content on TikTok, how prevalent liking behavior is on TikTok, and whether there are substantial differences across our participants’ demographics. We conclude our work by discussing the lessons learned and future avenues for implementing data donation systems, which we believe offer a promising avenue for collecting user behavioral traces to understand social phenomena through the lens of the Web.

## 1 Introduction

The Web is a constantly evolving ecosystem, with new media platforms proliferating and changing the way people consume information. One recent and notable addition to the ecosystem is TikTok, a short-form video platform revolutionizing the way people get entertained online by offering an endless stream of video recommendations. TikTok is widely popular, currently sitting at 1.3 billion users worldwide [16]. Academic research has quickly turned to focus on the platform, seeking to understand TikTok’s algorithm (e.g., [6]), content (e.g., [48, 19, 1]) and users (e.g., [18, 22, 26]).

Due to TikTok’s lack of external access (e.g., API) through which to conduct direct measurements, all of this research

must be conducted with external data. Prior work has gathered data by scraping the platform (e.g., [2, 19, 20]), an approach that can only collect a few thousands of videos, relies on publicly available information that are included on the web page’s source, and is usually biased towards popular videos; from self-reports (e.g., [18, 22, 26]), which suffer from known biases in social media research [27, 42, 9, 12]; or from researcher-created accounts [6, 35], which is a promising technique, but may yield data that ultimately lacks the authenticity, diversity, and account history that real user accounts would contain.

In this work, we offer a method for overcoming such data collection limitations via a novel measurement system for directly measuring the TikTok platform. Using this system, we conduct the first, to the best of our knowledge, measurement of people’s consumption and engagement with TikTok content. Our measurement approach combines the power of collective action with the protections offered by the EU’s General Data Protection Regulation (GDPR) [11] to design a TikTok data donation system. The GDPR describes the *right of access by the data subject* (Article 15), which allows individuals (i.e., users) to request and get access to all the data about them that the controller (i.e., social media platform) collects and processes. Should users have a means of donating their data for research, this opens new possibilities for undertaking research studies. Indeed, previous work leverage the rights of data subjects for data donations to study advertisements on Twitter [43] and the use of Instagram by adolescents [10]. These efforts, however, do not design and implement a data donation system; they rely simply on users uploading their files to a server. As the data includes many personal identifiers, having a data donation system is essential to better balance user privacy with data donation (i.e., by removing personal identifiers client-side), which may increase the likelihood of user data donation.

Our data donation system facilitates donations from TikTok users who request their downloadable data from the platform. Our donation system accepts data generated by the TikTok platform and allows users to anonymize and customize their data (i.e., select which fields of the data they want to donate) *before* donating their data to our infrastructure. This approach allows us to collect data on a user’s activity from the beginning

of their TikTok usage to the time they requested their data. The data includes a wide variety of fields, including the entire video viewing history and engagement activities (e.g., likes, shares, and comments on videos). These datasets are rich and provide us with an invaluable opportunity to study how people use TikTok, while maintaining user privacy.

In this work, we use our donation system to conduct a study of TikTok user behavior that seeks to understand how people behave on TikTok (e.g., how many videos people watch and how much time they spent on the platform), how prevalent is video engagement on TikTok, and whether there are significant differences across our participants’ demographics. We recruited 347 TikTok users (our study participants) to donate their data using our system, ultimately compensating our participants with \$6.9K USD. We find that participants watch a relatively large number of videos per day (median of 90 videos per day) and spend on average 27 minutes per day on TikTok. Compared to YouTube, this daily consumption is larger (based on one report, users spent 19 average daily minutes on YouTube in 2022 [24]), despite the fact that YouTube’s videos have a longer duration. Also, we find that younger participants (aged between 18-24 years old) spent more time on TikTok compared to older participants (e.g., aged between 25-34). This result prompts the need for further investigation into how younger people use TikTok, particularly, to investigate potential social media addiction. With regards to user engagement, we find that participants typically engaged with videos by liking them (vs. commenting or sharing) and that younger participants (aged between 18-24 years old) tend to ‘like’ more videos compared to older participants (aged between 25-34 years old).

**Contributions.** The contributions of this work are two-fold. First, to the best of our knowledge, we perform the first research study on TikTok that is based on data donated by real users. We shed light on how TikTok users behave on the platform and how prevalent their engagement is via video liking. As TikTok becomes increasingly popular, especially among younger people, such studies allow us to understand better how people are using this emerging platform. Second, we investigate the possibility of performing social media studies by leveraging data donated by the users themselves. By designing, implementing, and using a data donation system, we experience and surface challenges (e.g., malicious users) that exist in obtaining and analyzing data donated by real users. We discuss these challenges and the lessons we learned, which we believe will be of interest to the research community focusing on understanding closed social media platforms.

**Paper Organization.** Section 2 reviews previous work, while Section 3 describes our data donation system that facilitates data donations from real users. In Section 4.1 we report our recruitment procedures and in Section 5 we discuss our ethical considerations. Section 6 includes our analysis and results aiming to provide insights into how people behave on TikTok. Finally, we conclude and discuss our findings, potential implications, and lessons learned in Section 7.

## 2 Background & Related Work

### 2.1 TikTok

Known as Douyin in China, TikTok is a short-form video platform owned by parent company ByteDance. ByteDance first launched Douyin for China-based users in 2016, and launched TikTok as its international counterpart shortly after [39, 37]. The company acquired Musical.ly, a similar short-form video platform, in 2018, and in doing so enabled TikTok to expand its user base worldwide [39]. Since then, TikTok usage has continued to grow, rising to be the most downloaded app of 2020 [4]. At the time of this writing, TikTok sits at 1.3 billion monthly active users worldwide [16].

As a platform, TikTok allows users to both watch and create short-form videos up to 3 minutes in length (currently, the company is rolling out a 10-minute length option for select users [23]). TikTok offers multiple editing capabilities for creators, and allows users to connect with peers via following, messaging, and sharing content. One of the app’s most prominent characteristics is its ability to recommend relevant video content to viewers [33, 18]; when using TikTok, a user may scroll through two different content feeds, one containing videos posted by the people they follow (“Following”), the other a curated feed of content from many different creators (“For You”). Contents on the For You feed are served to users based on a user’s account information and behavior, the specifics of which are largely unknown to the public.

Much of the prior work on TikTok has studied the recommendation algorithm [40, 1, 6, 18, 35, 34], the content on the platform [3, 13, 28, 46, 19, 48, 37, 21, 44, 45, 31], and performed user studies on TikTok users [49, 32, 17, 18, 26, 8, 30, 22]. To the best of our knowledge, our work is the first to investigate user behavior through the lens of data donated directly from users using the rights of data subjects. These datasets allow us to obtain a holistic and unique view into how people behave on TikTok and how they engage with content on TikTok.

### 2.2 Data Donation

Per the EU’s GDPR [11], most major digital platforms now provide their users with electronic access to the personal data they have on each user, via downloadable data packages [7]. A prominent movement in the medical field [5, 36], researchers studying digital platforms are beginning to leverage the rich information in these packages by requesting that users donate them for study. Data donations offer unique insights into digital platforms [41]: for example, uncovering widely-used ad targeting mechanisms on Twitter that were largely ignored by prior work [43] and gaining new insights into how adolescents use Instagram [10] have all been possible via user data donation.

Motivations for using user-donated data stem from limitations of other methods. People’s perceptions of their own online behavior, for instance, can be unreliable [27, 42, 9, 12]. Additionally, researcher-created accounts on digital platforms may lack the authenticity, diversity and history that real user

accounts have. Further, scraping TikTok data yields fruitful data sets, yet has capacity limitations and totally relies on public – and typically, popular – content available on the platform. User-donated TikTok data can provide further insight into how real TikTok users are consuming content on TikTok. In this work, we design and implement a data donation system that facilitates data donations from TikTok users directly.

### 3 Data Donation System

We implement a data donation system, *Social Media Donator (SMD)*, where users can get information on how they can request their data from the TikTok mobile application. We provide details on how users can request their TikTok data and what is included in the data in Appendix A. After users download their data, they can use SMD to anonymize and customize their data *before* transferring the data to our infrastructure.

**Data Anonymization.** The data collected from TikTok includes personal information and identifiers for each user, such as phone numbers and email addresses. Due to this, it is essential to ensure proper anonymization of the data before transferring it to our infrastructure. To ensure the data is properly anonymized before it is transferred to our infrastructure, our SMD system removes certain information by default. This includes the user’s profile information, direct messages, information about videos uploaded, IP addresses and device information, purchase information, and account status. The anonymization process is done on the client side, and we emphasize that we only transfer the anonymized dataset to our backend. Additionally, we provide a Python script that allows users to anonymize and customize their dataset offline without using SMD. This script is identical to the one available in SMD and is intended for use by participants who are concerned about privacy.

**Data Customization.** TikTok users may have different levels of comfort in sharing certain data fields. For example, a user who frequently posts comments with personal information may not feel comfortable sharing their comment-related data. To address this, we have implemented a customization feature in SMD, which allows users to choose which fields of their data they are comfortable donating. The only mandatory field is the video viewing history, which includes only the URLs of the videos watched and the timestamps. Additionally, there are some fields that users are not able to donate, as they contain personal information and identifiers (as outlined in the data anonymization procedure). For the remaining fields that a user can choose to donate, we provide clear explanations of what data is included, with specific examples and a description of how we plan to use each field in our analysis. Additionally, for data fields that may contain sensitive information, we have added warning labels to alert users that the field may potentially include private information. For example, for the search history, we added a warning label that says "This information may be sensitive if you did uncommon searches for things related to your real identity, e.g., searching for videos of a family member’s small sports team." Similar warnings were added for

the followers, following, and comments data since these fields may reveal the user’s identity through their follower network and comments made on public videos.

SMD calculates the compensation for the user based on their selections of which fields of data they opt-in to donate. The mandatory video viewing history is compensated with \$5, while all the optional fields such as Like History, Search History, Share History, Login Information, App Settings, Comments, Favorites, Following, Followers, and Ads Information are compensated with \$1 each, except for comments. For comments, users have the option to either donate their comment timestamps and content for \$2 or only the timestamps for \$1. The total compensation for each user ranges from \$5 to \$16, depending on their selections.

**Data Donation & Survey.** Users can donate and transfer their anonymized and customized data to our infrastructure with a single click on the SMD interface. After the data donation, we present all users with an optional survey that includes general demographic questions and questions about their usage of the TikTok platform and their perceptions of the TikTok algorithm’s recommendations. This survey helps us to gain extra context on the users such as their age, gender, and location. It is important to note that all questions in the survey are optional, and users can choose to not answer by selecting the "Prefer not to say" option. All users who choose to fill out the survey will receive an additional compensation of \$4 regardless of the questions they choose not to answer.

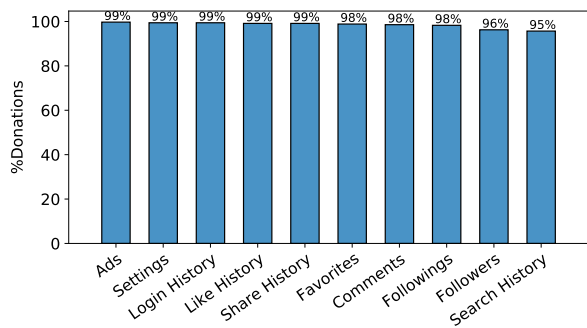

## 4 Data Collection

We present our approach to collecting data from TikTok users. We describe our recruitment process, metadata collection for TikTok videos, and our efforts to assess the quality of donated data.

### 4.1 User Recruitment

We recruited participants for the study in two ways: 1) by sharing the study through the authors’ networks on Twitter, and 2) by running Facebook Ads targeting people over 18 years old living in the U.S. who Facebook had tagged with the "TikTok" interest category. For the former, we created a poster to advertise the study and shared a single tweet that was amplified by all the authors’ Twitter accounts. The tweet was shared in January 2022 and received 64.5K impressions on Twitter. For the latter, we ran Facebook Ads between January 21, 2022, and February 13, 2022, with an average budget of \$8.5 per day. Using these two methods, we recruited 347 participants, whom we compensated with an overall amount of \$6.9K in the form of Amazon gift cards sent via email.

Fig. 1 shows the percentage of participants that opted-in to donate each potential field that exists in their TikTok data. As we can observe, most of our participants chose to donate almost all the fields, as all fields appear in at least 95% of all the donations. Participants were less willing to share their Search History (95%) and Followers (96%), Following (98%),

**Figure 1:** Percentage of donations that opt-in to donate to each field included in the TikTok data.

Region	# (%)	Age	# (%)
Africa	174 (52.2%)	25-34 years old	162 (48.6%)
N/C America	108 (32.4%)	18-24 years old	145 (43.5%)
South America	22 (6.6%)	35-44 years old	13 (3.9%)
Prefer not to say	19 (5.7%)	Prefer not to say	12 (3.6%)
Europe	10 (3.0%)	45-64 years old	1 (0.3%)
Gender	# (%)	Education	# (%)
Men	183 (54.9%)	Bachelor’s or above	181 (54.3%)
Women	144 (43.2%)	Associate’s degree	58 (17.4%)
Non-binary	3 (0.9%)	Some college	51 (15.3%)
Prefer not to say	2 (0.6%)	HS or below	26 (7.8%)
Self-described	1 (0.3%)	Prefer not to say	15 (4.5%)
-	-	Trade school	2 (0.6%)

**Table 1:** Demographics of the participants that completed our survey (96% of all participants). “Prefer not to say” refers to users that opted out from answering that question in the survey, while “N/C America” refers to “North/Central America.”

and Comments (98%). This is potentially due to the warning labels associated with these fields in our SMD interface, explaining that some information included in these fields might be sensitive (see Section 3). This result suggests that most participants perceive the trade-off between the compensation and the donation of additional fields as worthwhile.

**Participants’ Demographics.** Participants self-reported their demographics via an optional survey (see Section 3). Note that 14 out of 347 participants (4%) opted out from completing the survey, hence we do not have any demographic information about them. Table 1 provides an overview of our participants’ demographics.

About the reported region in which they reside, we observe that just over half of our participants are from Africa (52%), while the remainder is from North/Central America (32%), South America (6.6%), and Europe (3%). Interestingly, many of our participants were from Africa despite the fact that we mainly targeted Facebook users living in the U.S. We hypothesize that the monetary incentives may have been relatively more substantial for users from Africa highlighting that people from under-developed countries can be attracted by the monetary incentives to participate in research by donating their data. With regards to the age of our participants, we note that the majority of our participants are 34 years or younger (91%),

	#Participants	#Actions
<b>Video Viewing History</b>	347	9,212,100
<b>Like History</b>	328	1,120,716
<b>Search History</b>	332	13,282
<b>Share History</b>	253	24,944
<b>Comments</b>	227	52,436
<b>Following</b>	333	84,654
<b>Followers</b>	295	43,642

**Table 2:** Overview of our dataset. We report the number of participants with at least one action.

with 48.6% of the participants aged between 25-34 years old and 43% of the participants aged between 18 and 24 years old. Note that given the popularity of these age groups in our participant set, we focus our demographic analysis in Section 6 on the 18-24 years old and 25-34 years old age groups only. Our participants set is somewhat gender-balanced with 55% of the participants being men, while 43.2% of our participants are women and 1.2% are non-binary or self-described their gender. Note that we compare only men and women in the gender analyses presented in Section 6, as we do not have sufficient statistical power to make comparisons between people of other genders. Finally, most of our participants are educated with 54% having a bachelor’s degree or above (e.g., MSc or PhD), 32% have completed some post-high school coursework or completed an associate’s degree or country equivalent.

**Dataset.** Table 2 reports an overview of our dataset; it includes 9.2M video views from 347 participants, between July 26, 2020 and February 21, 2022. Our dataset also includes 1.1M like actions from 328 participants, 13K search actions from 332 participants, 24.9K shares from 253 participants, 52.4K comments from 227 participants, 84.6K following actions (i.e., the participant started following a user) from 333 users, and 43K follower actions (i.e., a TikTok user started following one of our participants) from 295 participants. Also, we note that by looking into how these actions appear over time in our dataset, we find that there is a 2-month gap for the like actions data. That is, there is no likes information for any of the 347 recruited participants, likely because of issues with the logging infrastructure within TikTok. Also, we find that information about sharing videos is only included in the data after July 28, 2021.

## 4.2 Video Metadata Collection

Each participant’s data includes information about their activity, including the videos they watched, liked, shared, etc. Note that for each video, the data only includes a video URL. To obtain more context and metadata about the TikTok videos that are included in our donations, we scrape each video’s TikTok webpage. Specifically, we use an unofficial Python API wrapper [38] that essentially uses Selenium to scrape the TikTok page for each video and provide the video’s metadata in JSON format. Overall, in our 347 donations, we find 4,938,805 unique TikTok videos viewed by our participants. We attempted to collect the metadata for all of the videos, man-

aging to obtain metadata for 4,122,038 videos (83.4% of all videos). The rest of the videos were either deleted by the uploader or TikTok itself, or the account that posted the videos set their account into private mode. Since participants' data donations include their entire activity, we collect videos from 2020, which are more likely to be deleted compared to newer videos. We ran our metadata collection between January 17, 2022, and March 12, 2022. For each video, we collected the following metadata: 1) Video creation timestamp; 2) Video description and title (defined by the uploader); 3) Information about the uploader such as the uploader's username and unique identifier; 4) Video metadata such as video duration, video format, definition (e.g., 720p), etc.; and 5) Video statistics such as the number of shares, comments, and number of times that the video was viewed (at the time of our crawl).

### 4.3 Assessing the “Quality” of Donations

SMD requires participants to provide an email, for the purposes of sending the compensation. We also use the MD5 hash of each email as the unique identifier for each donation. Note that we do not link the email address explicitly with the donation for anonymity purposes. As expected with studies that offer a monetary incentive, users may try to “trick” the system to earn money easily. Indeed, during our recruitment, we noticed that some TikTok users were trying to earn more money by donating duplicate or near-duplicate data under different email addresses. To detect such malicious donations, SMD calculates all the pairwise Jaccard similarities between the video URLs and timestamps that are included in the video viewing history. Then, SMD flags the donations that have a Jaccard similarity of over 0.2 for either the video URLs or the timestamps, and then we manually check the donations to verify that are indeed duplicate or near-duplicate donations. This process is done before sending the compensation. Overall, we received 31 duplicate or near-duplicate donations (all of them having a Jaccard similarity of 0.9 or more) that would have cost us \$571. For these donations, we did not pay users, and we informed them via email that they would not receive compensation for all their subsequent duplicate donations (as they already received compensation previously).

Another concern that we have is that malicious users can generate fake video URLs and fake timestamps to try and donate fake data for compensation. To verify if this is happening in our recruitment, we check for what percentage of each donation's videos we were able to obtain video metadata. Here, we hypothesize that if a malicious user generates fake URLs then we will not be able to get any metadata for the videos included in the donation (since the URLs will not exist). We did not find any evidence of users submitting fabricated donations, since for all the donations we were able to obtain metadata for a large percentage of the videos — at least 70% for every donation, with a median of 90%. As discussed above, the rest of the videos were inaccessible because they were either deleted or the account became private.

## 5 Ethical Considerations

Before recruiting participants and collecting any data from real TikTok users, we obtained approvals from two different Ethical Review Board committees (one from a university in Europe and one from a university in the US). We provided to the Ethical Review Board committees a detailed document explaining all the various data fields included in the TikTok data, our anonymization/customization procedures, the consent form that is presented to the users, as well as our advertisements for recruiting users.

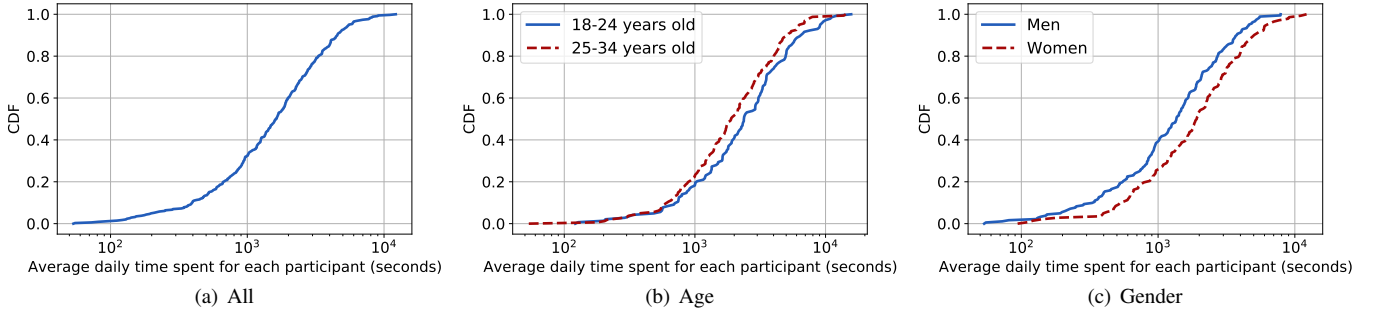

For each recruited user, we obtained explicit consent by providing them with a consent form (which can be downloaded via our SMD donation system) and by requesting the users to acknowledge that they fully understand the content of the consent form and that they allow us to store their data. Additionally, as noted in Section 3, for each data field we explained to the participants how we are planning to use the data included in their data and the potential privacy implications of donating some fields of the data (e.g., comments, search history, and follower/following network). As mentioned in the previous section, all users that donated their data got a compensation using Amazon gift cards between \$5-\$20 depending on the fields of their data they opted-in to donate and whether they filled in the optional small survey.

We will permanently delete all user data within 36 months after the end of our project and the collected data will not be distributed to any third parties. Also, we emphasize that the users have the power on their hands with regard to what specific fields of data they opt-in to donate. For our analysis, we follow standard ethical guidelines [29] like reporting our results in aggregate and not attempting to track users across platforms. Finally, our metadata collection focuses only on publicly accessible videos that are available on the TikTok platform during the data collection period (i.e., we do not collect any information about private videos or deleted videos).

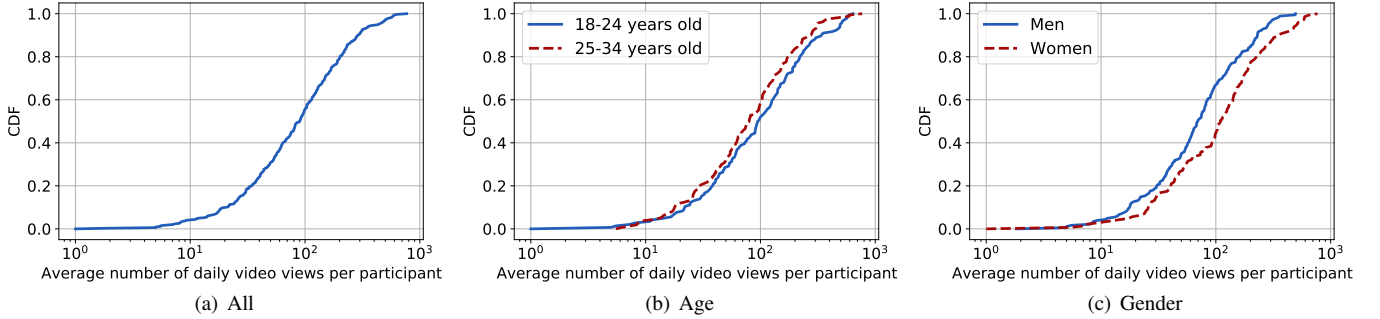

## 6 Results

In this section, we present our analysis and results focusing on understanding how users behave on TikTok, particularly, assessing how many videos they watch, how much time they spent on the platform, how many videos each participant liked, and whether there are substantial differences on user behavior across demographics.

**Method.** We compute two metrics to measure consumptive behavior: *Time Spent* and *Volume*. To compute *Time Spent* on the platform, we need to infer an approximation of the watching duration of each video view based on the timestamps since the donated data only contains information on when each participant started watching each video (see Appendix A on what is included in the data). To do this, for each video, we calculate the number of seconds between the time that the participant started watching a video and the time that the participant started watching the next video. This allows us to obtain an approximation of the viewing duration of each video, except for

**Figure 2:** CDF of the average time (in seconds) that our participants spent watching TikTok videos per day.

**Figure 3:** CDF of the average number of daily video views per participant.

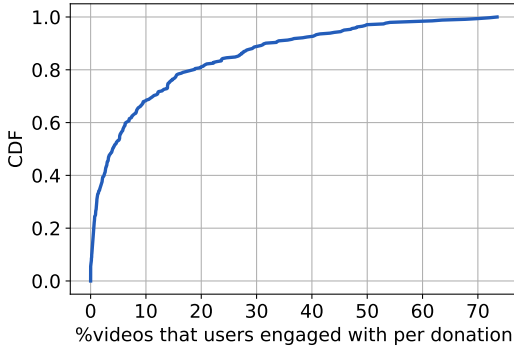

the last video of each session: when the user takes a break, we would infer the viewing time of the last video of the session to be unrealistically long. Unfortunately, we cannot simply use the duration of the video itself to identify session breaks, because we do not have duration metadata for all videos, and because on TikTok, videos automatically start again and loop if users do not scroll to the next one. Instead, we set the threshold for identifying session breaks to 105 seconds (1.75 minutes) following the methodology by Halfaker et al. [15]. The main idea of the method is that one can perform user session identification (i.e., when users take breaks) based on inter-activity times by performing a two-component Gaussian mixture model clustering using the expectation-maximization algorithm [25].

By obtaining the results from this clustering, we can identify the cutoff threshold between the two clusters, which in our TikTok dataset is equal to 105 seconds. This means that whenever a participant appears to spend more than 105 seconds on a video, then we infer that they took a break and this marks the end of a session — in this case, we are unable to infer the time that the participant devoted to that specific video. This threshold is substantially smaller compared to the one found by Halfaker et al. [15] on Wikipedia (about 1 hour). This is mainly due to the fundamental differences between the two platforms, as people tend to spend more time on a Wikipedia article than a TikTok video. Indeed, by looking at the inferred viewing durations and all video durations (obtained from the video metadata), we find that 98.5% of all the inferred viewing durations are 105 seconds or less. At the same time, only a small fraction of the videos have a duration of over 105 seconds (1.8% of all videos). Note that we experimented with larger thresholds (be-

tween 100 seconds and 600 seconds); the main insights from our results were the same, hence we report the results with 105 seconds as our threshold. Second, we compute a *Volume* metric: the average number of videos each participant watched per day.

**Time Spent.** We start our analysis by looking into how much time our participants spend on TikTok. Fig. 2 shows the Cumulative Distribution Function (CDF) of the average time spent per day for each participant. For each participant, we calculate the sum of the inferred durations for each day that they used TikTok, and then we calculate the average time across all days. For all participants (see Fig. 2(a)), we find a median value of 1,622 seconds per day (27 minutes), with 25% of our participants ( $Q1$ ) spending on average less than 834 seconds per day (13.9 minutes) on TikTok, while the 25% most active ( $Q3$ ) participants spent 2,891 seconds (48 minutes) or more ( $\sigma$ : 1,864 seconds). The most active participant in our dataset spent, on average, 12,186 seconds per day (3.3 hours).

We also investigate if there are differences across participants based on their demographic information (see Fig. 2(b) for age and Fig. 2(c) for gender). We find that participants aged between 18-24 years old spent more time on TikTok (*median*: 1,821 seconds,  $Q1$ : 948 seconds,  $Q3$ : 3,131 seconds,  $\sigma$ : 2,008 seconds) compared to participants aged between 25-34 years old (*median*: 1,423 seconds,  $Q1$ : 749 seconds,  $Q3$ : 2,667 seconds,  $\sigma$ : 1,771 seconds). To assess the statistical significance of our results, we perform a Mann-Whitney U test on the distributions finding that the differences between participants aged between 18-24 years old and 25-34 years old are statistically significant ( $p < 0.05$ ). With regards to the gender-related results (see Fig. 2(c)), we find that women (*median*:

**Figure 4:** Percentage of videos that the participants liked per donation.

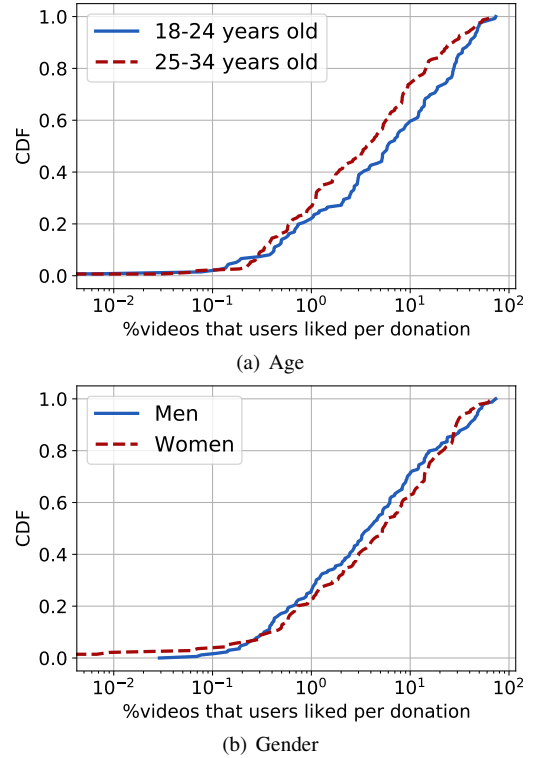

1,917 seconds,  $Q1$ : 962 seconds,  $Q3$ : 3,243 seconds,  $\sigma$ : 2,109 seconds) spent more time on the platform compared to men (median: 1,360 seconds,  $Q1$ : 728 seconds,  $Q3$ : 2,432 seconds,  $\sigma$ : 1,452 seconds). These results are statistically significant, as confirmed by a Mann-Whitney U test ( $p < 0.01$ ).

**Volume.** Next, we analyze the volume of videos watched by participants. Fig. 3(a) shows the CDF of the average number of video views per participant, for all participants, while Fig. 3(b) and Fig. 3(c) show the same results for participants grouped by the gender and age groups we compare, respectively. We observe that, on average, our participants watch a substantial number of videos per day, with a median of 89.9 videos per day ( $Q1$ : 40.7 videos,  $Q3$ : 170.3 videos  $\sigma$ : 128.9 videos). This is somewhat expected since TikTok videos are usually short in length, hence users can watch a large number of videos without spending much time (compared to other video platforms like YouTube). We also investigate the differences across age groups and gender (see Fig. 3(b) and Fig. 3(c)), finding that, among our participants, women watched significantly (MWU all tests  $p < 0.01$ ) more videos on TikTok than men.

**Liking behavior.** From the statistics in Table 2, we can extract some valuable insights into user engagement on TikTok. Our dataset’s most popular engagement action is liking videos, with 1.1M actions. This is a substantially larger number than other engagement actions, such as shares (24K) and comments (52K). Given the popularity of these engagement actions and their temporal coverage (see Dataset in Section 4), throughout the rest of the paper, we focus on likes when we study our participants’ engagement with videos.

We look into the prevalence of likes on a per-participant level. Fig. 4 shows the Cumulative Distribution Function of the percentage of videos that were liked per participant (for the ones that opted-in for donating to each of these engagement-related fields). We find a median of 4% of videos that are liked per donation ( $Q1$ : 0.87%,  $Q3$ : 14.09%,  $\sigma$  : 15.03%).

We also investigate differences in liking prevalence on TikTok across our participants’ demographic attributes. Fig. 5 shows the CDF of the percentage of videos that are liked by each participant across the ages and genders we compare. We observe similar results as with the consumptive behavior focusing on the number of videos or time spent on the platform;

**Figure 5:** Percentage of videos that the participants liked across our demographic attributes.

1) Participants aged between 18-24 years old tend to like more videos (median: 5.8%,  $Q1$ : 1.2%,  $Q3$ : 23.6%,  $\sigma$ : 16.6%) compared to the participants that are between 25-34 years old (median: 3.6%,  $Q1$ : 0.9%,  $Q3$ : 10.5%,  $\sigma$  : 13.5%) or older (median: 4%,  $Q1$ : 1.5%,  $Q3$ : 14.5%,  $\sigma$ : 14.8%). This difference in engagement between the age groups is statistically significant with  $p < 0.05$ ; 2) We find no statistically significant differences ( $p = 0.15$ ) in participants’ liking behavior for men and women.

**Take-aways:** The main take-away points from our analysis are:

- Our participants spent a considerable amount of time watching videos on TikTok per day (median time spent: 27 minutes, median number of videos: 90 videos). This consumption is larger compared to other video platforms like YouTube, where people spend on average 19 minutes [24]. Also, we find that participants aged between 18-24 years old tend to spend more time on the platform than participants aged between 25-34 years old. This difference in consumptive behavior highlights the need for more research efforts on understanding user consumptive behavior in young people, especially in teens (an age group that we do not analyze here and might be more prone to addiction from TikTok). Finally, we find that women tend to spend more time and watch more videos on TikTok compared to men.
- By far the most popular engagement action is liking a video with sharing and commenting on videos having a

substantially smaller prevalence in our dataset. Also, we find statistically significant differences in the liking behavior of participants aged between 18-24 years old compared to participants aged 25-34 years old (i.e., younger participants tend to like more content on TikTok).

## 7 Discussion & Future Work

Below, we discuss our TikTok user behavior measurements and lessons for future data donation efforts.

### 7.1 Observing TikTok Behavior

Our work is a stepping stone to understanding how people consume and engage with content on TikTok, based on traces from real users via data donations. Our analysis shows that our participants spend a considerable amount of time per day on TikTok and watch many videos, more so than on other popular video platforms like YouTube [24]. They engage with videos to a relatively limited extent: a median of 4% of videos were liked per donation, and likes were significantly more prevalent than other engagement actions such as shares and comments.

Our quantitative findings and data collection methodology can assist future investigations that analyze content and/or participant experiences. For example: What is the impact of TikTok’s algorithm on users, and to what extent do the recommendations lead to informational rabbit holes? What is the content that people of different demographics engage with? What actions do users take to influence TikTok’s recommendations (e.g., intentionally skipping videos or following certain accounts), and how effective are those actions? What is the role of ads on TikTok [14, 47]? Future research may also wish to consider additional demographics than those explored in our study.

### 7.2 Data Donation System

Here, we summarize future directions for and lessons learned from designing and deploying our data donation system.

**User recruitment.** In this work, our initial goal was to recruit participants exclusively from the U.S., which is why we targeted people from the U.S. on Facebook and explicitly mentioned that we were recruiting U.S. people in our Twitter post. Despite our initial goal and our ads, our data donation system was publicly available to anyone, and we did not limit access to people coming from specific regions. Hence, we obtained a substantial number of participants from other regions as well (e.g., Africa). Future work that aims to recruit participants from specific regions or with other restrictions should implement measures that ensure participants meet the study’s requirements. One way to do this is by limiting the access to the system to specific IP addresses that come from the region/country of interest.

**Malicious users and assessing the quality of donations.** During our recruitment and data donation procedures, we noticed several instances of malicious users trying to “trick the system” to get extra monetary incentives. We identified three

cases of malicious users: 1) users donating duplicate data (i.e., donating the same data multiple times with different email addresses) to get extra monetary incentives; 2) users donating their data, then using TikTok for a few more days, and then trying to donate their data again (i.e., duplicate data for the entire period except the few extra days at the end of the data); and 3) users creating new TikTok accounts, watching only a few videos on TikTok, and then trying to donate their data via our donation system. Based on these observations, we make the following recommendations. Researchers implementing data donation systems should design and implement specific countermeasures to detect malicious users that try to donate “useless” data. Concretely, developers of data donation systems should implement features to detect duplicate or near-duplicate donations, similar to the ones we implemented. In addition, to overcome the problem of people creating new accounts for the sake of donating their data, data donation systems can be developed in such a way so that they only accept donations that meet a minimum number of days of activity. For instance, in our case, our donation system rejected all donations where the donation lifespan (i.e., the difference between the last video view and first video view) was less than three months. Finally, in our work, we did not notice any attempts to donate completely fabricated data (e.g., randomly computer-generated video URLs and timestamps). However, we argue that this possibility exists, and tech-savvy malicious users may use some techniques in the future depending on how much money they can make from this activity.

**Pricing mechanisms.** Our experience recruiting people to donate their data for research purposes with monetary incentives, highlights that those from countries where the incentives offer more purchasing power (e.g., African countries) may be more willing to donate their data. More broadly, an essential aspect of data donation infrastructures is the underlying pricing mechanism, since this may affect how willing potential participants will be to donate their data. For our data donation infrastructure, we set some pre-defined compensation amounts for the viewing video history (\$5), as well as all optional fields (\$1 for each field). We thought that these prices are reasonable for our purpose and what was asked from the participants. However, future work is needed to empirically understand the interplay between data donation and pricing.

**Trustworthiness of the data donation system.** The degree of trust between the participants and the data donation system is likely to affect participant recruitment. We made two design choices in an effort to enhance participant trust. First, we provided offline tools that participants can run to anonymize and customize their data before using our data donation system. Second, we offer users control over which fields to donate. Nevertheless, future work on data donation systems should investigate which, if any, of these measures enhance user trust and explore additional measures that may appeal to users such as stronger formal guarantees that the data donation code is working as described and allowing only the access and queries participants expect to be run on their data.

**Missing data and the need for compliance audits.** By col-

lecting and analyzing user-donated data from TikTok, we noticed some missing data for all the participants (i.e., there were no like data for two months). The missing data might be due to failures in the logging infrastructure within TikTok or due to lost data. Nevertheless, this prompts the need for systematic audits of social media platforms to assess the platforms' compliance with the access rights of data subjects. Future work can design controlled experiments to assess how accurate and comprehensive the data provided by platforms is; e.g., by using the platform to perform some pre-defined actions, then accessing the provided data and comparing it with the set of pre-defined actions.

### 7.3 Limitations

Naturally, our work has some limitations. First, our recruitment procedure and research budget allowed us to obtain data from a small number of participants (347). We did not cover a full range of user demographics (e.g., age, gender, geography, etc.). Due to a lack of public information about the demographics of TikTok's user base, we cannot draw conclusions about the representativeness of our sample. Despite this critical limitation, our results offer a first measurement-based investigation into how people consume and engage with content on the TikTok platform. At the same time, the lessons learned from designing and implementing a data donation system can provide valuable insights to researchers that aim to collect data using similar approaches. Second, our video metadata collection is (necessarily) done post-hoc, hence we are unable to obtain a holistic view of all videos referenced in the data donations since approximately 17% of all videos were not accessible during our video metadata collection period. Third, even though the data donations are quite detailed, some of our results are based on inferences, such as the inferred time that each participant spent watching videos. Due to this, we are unable to accurately infer the viewing durations for video views that are above our determined threshold following the methodology by [15]. Therefore, our results based on the time spent on the platform should be considered lower-bound results, as we exclude all the video views at the end of each inferred session.

Many of our limitations reflect fundamental challenges with data donation as a way to externally study and audit closed platforms: our investigation was often limited by intentional or unintentional (e.g., the gap in "like" data) omissions in the data provided by TikTok's data download feature. Hence, as the research community and data protection regulation communities consider the role of data donation in platform transparency and auditing, we must also critically assess the quality and goals of the data downloads that platforms provide to comply with data protection laws.

## A Requesting Data from TikTok

TikTok enables its users to request a comprehensive dataset of their activity on the platform and other personal information the platform has on them. The request can be made through the TikTok mobile application’s settings menu, and the data will be provided in either JSON or a human-readable format based on the user’s preference. The process takes around 3-4 days for the data to be ready for download. Here we outline the various fields of information included in a user’s TikTok data download.

- **Video Viewing History:** A list of videos and the timestamp that the user started watching each video.
- **Like History:** A list of videos that the user liked and the timestamp of each like action.
- **Search History:** A list of search queries that the user performed in TikTok, including a timestamp of each search action.
- **Share History:** A list of videos that were shared by the user, along with the timestamp of the action, and the method for the share (e.g., shared via WhatsApp or Facebook Messenger, etc.).

- **Login Information:** A list of login information for each time the user started using the TikTok app. For each login, the file includes the timestamp, the IP address from where the user performed the login, information about the device (device model and device system), network type (e.g., WiFi, mobile data, etc.), and the carrier.
- **App Settings:** Information about the settings that the user set on TikTok. For instance, the interests that the user pre-defined in the TikTok application and privacy settings (e.g., whether the account is private, who can comment on their videos, who can message them, etc.)
- **Comments:** A list of comments made by the user along with the timestamp of the action. Note that the file does not include the specific video where the comment was posted.
- **Favorites:** A list of videos, effects, hashtags, sounds, and videos that the user favorited on TikTok including the timestamp of each action.
- **Following/Followers:** A list of accounts that the user follows/follow the user along with the specific timestamp of the follow action
- **Ads Information:** Information about the advertisers that targeted the user.
- **Profile Information:** A set of profile attributes that the user set on the TikTok application. It includes the user’s bio, email address, telephone number, username, profile photo, etc.
- **Direct Messages:** A list of messages shared via private chats between the user and other TikTok users.
- **Video Uploads:** A list of the user’s uploaded videos.
- **Purchase History:** Information about the purchases made by the user within the TikTok platform.
- **Account Status:** Information about the status of the TikTok application on the user’s phone (e.g., application version, screen resolution, etc. )
