Table S1. Site-specific inclusion criteria

| Cohort | Country | Diagnosis measurement | Sample criteria $\quad$ characteristics/inclusion | Exclusion criteria |
| :---: | :---: | :---: | :---: | :---: |
| ASRB | Australia | Diagnosis was confirmed using the OPCRIT algorithm applied to interviewer ratings on the DIP, acc. to ICD-10 criteria | All participants were fluent English speakers and aged 18-65 years old | No history of an organic brain disorder, brain injury accompanied by $>24 \mathrm{~h}$ of amnesia, mental retardation defined as an IQ $<70$, movement disorder, current substance dependence, or electro- convulsive therapy in the preceding 6 months. The control participants additionally had no personal history of psychotic disorder or family history of psychotic disorder in their first-degree biological relatives. |
| CAMH | Canada | SCID DSM-IV-TR Axis I | Schizophrenia outpatients who were clinically stable as determined by no medication change within the past month | Exclusion criteria were intelligence quotient $<70$ as estimated by the Wechsler Test for Adult Reading (WTAR), substance dependence or abuse reported or indicated by a urine toxicology screen, head trauma with loss of consciousness, neurological disorders, and any magnetic resonance imaging contraindications. A first degree relative with a primary psychotic disorder was also an exclusion criterion for controls. |
| CIAM | South <br> Africa | SCID DSM-IV-TR Axis I | Stable outpatients between ages 1940 years with a diagnosis of schizophrenia or bipolar type I disorder with psychotic features or methamphetamine induced psychotic disorder or controls without a history or family history of psychotic symptoms. | Patients were excluded if they had a psychotic disorder other than schizophrenia or bipolar type I with psychotic features or methamphetamine induced psychotic disorder (i.e., schizophreniform disorder). Patients or controls were excluded if they had a physical condition requiring medication, prior head trauma or neurosurgery, any history of a cardiovascular event, a history or family history of epilepsy, a learning disability, if they were pregnant or lactating, or had any metal brain implants. Patients with bipolar type II disorder were excluded. Patients in the methamphetamine psychosis group were excluded if there was any evidence of symptoms persisting longer than 1 month after the cessation of methamphetamine use or if there was evidence of prior psychotic symptoms not related to the use of methamphetamine. |
| COBRE | USA | SCID DSM-IV Axis I Disorders | All participants were in the 18-65 age range and had a diagnosis of schizophrenia. Healthy individuals were included if they did not have a personal or family history of psychiatric disorders. | History of neurological disorder, history of mental retardation, history of severe head trauma with more than 5 minutes loss of consciousness, history of substance abuse or dependence within the last 12 months and MRI contraindications. |
| ESO | Czech Republic | ICD-10 (F20.x, F23, F25) | Early or first-episode psychosis, Czech language as a mother tongue, 18-60 years old | Neurocognitive disorders (organic mental disorder), mental disorders caused by addiction, mental retardation ( $\mathrm{IQ}<80$ ), severe neurological disorder, head injury, hypertension, cerebrovascular disease, epilepsy, migraine, endocrine disorders. |
| FOR210 <br> Marburg | Germany | Semi-structured interview <br> using SCID DSM-IV-TR <br> Axis-I Disorders  | All participants were aged between 1865 and were fluent German speakers. Patients (in-and out-patients) had a | Exclusion criteria were any history of neurological (head trauma or unconsciousness) andmedical condition (severe somatic disorders), magnetic resonance imaging |

|  |  |  | lifetime diagnosis of schizophrenia. Healthy individuals were included if they did not have any lifetime history of psychiatric disorders. | contraindications, verbal IQ $<80$ (assessed using MWT-B), current substance dependence or benzodiazepine treatment. |
| :---: | :---: | :---: | :---: | :---: |
| FOR210 Muenster | Germany | Semi-structured interview <br> using SCID <br> Axis-I Disorders DSM-IV-TR | All participants were aged between 18-65 and were fluent German speakers. Patients (in-and out-patients) had a lifetime diagnosis of schizophrenia. Healthy individuals were included if they did not have any lifetime history of psychiatric disorders. | Exclusion criteria were any history of neurological (head trauma or unconsciousness) and medical condition (severe somatic disorders), magnetic resonance imaging contraindications, verbal IQ $<80$ (assessed using MWT-B), current substance dependence or benzodiazepine treatment. |
| FIDMAG | Spain | DSM-IV criteria based on interview and review of clinical history | Patients had a diagnosis of schizophrenia. All participants were in the 18-65 age range. | Controls were excluded if they reported a history of mental illness and/or treatment with psychotropic medication. Patients were excluded if have had a history of brain trauma or neurological disease or had shown alcohol/ substance abuse within 12 months before participation |
| FSLRome | Italy | SCID DSM-IV Axis I <br> Disorders (SCID-I) andSCID <br> DSM-IV Axis <br> II Disorders <br> Personality (SCID-II)  <br>   | Inclusion criteria were (i) age between 18 and 65 years; (ii) at least five years of education; and (iii) suitability for MRI scanning. | Exclusion criteria were (i) history of alcohol or drug abuse in the two years before the assessment; (ii) lifetime drug dependence; (iii) traumatic head injury with loss of consciousness; (iv) past or present major medical illness or neurological disorders; (v) any (for HC) or additional (for patients) psychiatric disorder or mental retardation; (vi) dementia or cognitive deterioration according to DSM-IV-TR criteria, and Mini-Mental State Examination (MMSE) score $<25$, consistent with normative data in the Italian population; <br> (vii) not able and willing to give written informed consent. |
| GIPSI | Colombia | DSM-IV-TR diagnosis criteria using the Diagnostic Interview for Genetic Studies (DIGS) | Subjects with diagnosis of Schizophrenia, between the ages of 18 and 60 years old. | History of traumatic brain injury, personality disorders or autism spectrum disorders. |
| IGP | Australia | Diagnosis was confirmed using the OPCRIT algorithm applied to interviewer ratings on the DIP, acc. to ICD-10 criteria | All participants were fluent English speakers and aged 18-65 years old | General exclusion criteria included an inability to communicate sufficiently in English, a current neurological disorder, a diagnosis of substance abuse or dependence in the pastsix months; and/or having been treated with electroconvulsive therapy in the previous six months. |
| MCIC | USA | SCID DSM-IV (SCID-NP for controls) or CASH were used to diagnose primary and comorbid psychiatricdisorders in controls and patients | All subjects were between the ages of 18 and 60 and spoke English as their native language. To be included in the schizophrenia cohort, patients had to meet diagnostic criteria for schizophrenia, schizoaffective disorder, or schizophreniform disorder. Concerted effort was made to recruit | Control subjects who met criteria for current or past history of substance abuse or dependence were excluded from the study. Patients, however, were not excluded from the study unless criteria were met for current (i.e., within the past month) abuse or dependence (except for 6 patients who were found to meet criteria for current abuse after the study data was collected). Both patients and controls were excluded if they had (1) an IQ less than 70 based on a standardized IQ test, (2) history of a head injury resulting in prolonged loss of consciousness, neurosurgical procedure, neurological disease, history of skull fracture, |

|  |  |  | patients early in the course of their illness and especially those who were antipsychotic drug naïve. The healthy control subjects with no current or past history of psychiatric illness including substance abuse or dependence were matched within site to the patient cohort for age, sex, and parental education. Control subjects who had not been diagnosed with any psychiatric disorders, but had been medicated with antidepressants, anti- anxiety medication or medication for sleep disturbance were included in the study provided that the duration of their medication did not exceed 2 months of lifetime use and no medication was used within the 6 months preceding the baseline MRI scan. | pregnancy, metal in body or head including implanted pacemaker, medication pump, vagal stimulator, deep brain stimulator, implanted TENS unit, or ventriculo -peritoneal shunt |
| :---: | :---: | :---: | :---: | :---: |
| MPRC | USA | SCID DSM-IV combined with a review of medical records | Individuals diagnosed with schizophrenia or schizoaffective disorder; and healthy controls without current DSMIV Axis I psychiatric illnesses. | The exclusion criteria included diagnosis with hypertension, hyperlipidemia, type 2 diabetes, heart disorders, major neurologic event such as stroke or transient ischemic attack, and recent substance use disorder (except tobacco and marijuana use). |
| OLIN | USA | SCID DSM-IV | AA: Participants (ages 18-70) were healthy controls and individuals with a DSM-IV diagnosis of schizophrenia or schizoaffective disorder. Healthy controls were allowed to have common psychiatric disorders (exceptfor any type of psychosis). <br> BSNIP: Participants (ages 15-65) were recruited from 5 sites (Hartford, Baltimore, Chicago, Dallas, Boston) and included healthy controls, individuals with a DSM-IV diagnosisof schizophrenia, schizoaffective disorder. Healthy controls had no | AA: Exclusion criteria for all subjects included a history of major medical disorders, severe head injury, MRI contraindication, IQ $<70$, dementia, traces of drugs (excluding THC) in urine, or drug intoxication during cognitive or MRI assessment. <br> BSNIP: Exclusion criteria for all subjects included history of seizures or head injury with loss of consciousness >10 minutes; positive urine drug screen for common drugs of abuse on the day of testing; diagnosis of substance abuse in the past 30 days or substance dependence in the past 6 months; history of systemic medical or neurological disorder likely to affect cognitive abilities; age-corrected Wide-Range Achievement Test, 4th edition, reading test standard score $<65$; and $<6$ th grade English reading level. <br> BPP: Exclusion criteria for all subjects included alcohol or drug abuse or dependence within the past 6 months, a history of major medical or neurological disorders, or IQ $<70$ as assessed by the WAIS. |

|  |  |  | personal or family history (first degree) of psychotic disorders; no personal history of recurrent mood disorder; no lifetime history of substance dependence; and no history of any significant cluster A Axis II personality features defined bymeeting full criteria or within 1 criterion of a cluster A diagnosis usingthe Structured Interview for DSM-IV Personality. We provided healthy control and SZ data only from theHartford site. <br> BPP: Participants (ages 18-70) were healthy controls. Healthy control subjects were included if they had nolifetime history of axis I psychiatric disorders as assessed by the SCIDand no family history of mood or psychotic disorders. |  |
| :---: | :---: | :---: | :---: | :---: |
| PAFIP | Spain | SCID DSM-IV for patients <br> confirmed by an independent psychiatrist 6months after the initial contact. CASH for controls. | Patients had to meet the following criteria: (1) age 15-60 years; (2) living in the catchment area; (3) experiencing a first episode of psychosis; (4) no prior treatment with antipsychotic medication or, if previously treated, a total lifetime of adequate antipsychotic treatment of less than 6 weeks; and (5) meeting DSM-IV criteria for schizophrenia, schizophreniform disorder, briefpsychotic disorder, or schizoaffective disorder. | Patients were excluded when meeting DSM-IV criteria for (1) drug dependence (except nicotine dependence), (2) mental retardation, and when having a history of neurological disease or head injury. Controls exclusion criteria were current or past history of psychiatric, neurological or general medical illnesses, including substance dependence and significant loss of consciousness. HCs were selected to have a similar distribution in age, sex, laterality index, drug history and years of education as the patient population. The absence of psychosis in first-degree relatives was also confirmed by clinical records and family interview. After a detailed description of the study, each subject gave written informed consent to participate. |
| PENS | USA | SCID for DSM-IV and DIGS Psychosis module performed by a trained clinical interviewer. Then all clinical materials | The sample included individuals with a schizophrenia spectrum disorder ( n $=35$ ) or bipolar disorder, first degree biological relatives of persons with a schizophrenia spectrum or bipolar | Participants were native English speakers, 18 to 60 years old, with normal or corrected hearing and vision, and IQ of at least 70. Participantswith a history of intellectual disability were excluded. Patients and controls were additionally excluded for substance abuse or dependence. within the past 6 months; history of electroconvulsive therapy, epilepsy, |

|  |  | reviewed by doctoral and graduate psychologists to achieve a consensus diagnosis. | disorder, and healthy controls. Participants were recruited from the Minneapolis Veterans Affairs Health Care System (VAHCS) and mental health centers in the Minneapolis community as part of a larger research protocol that included neurocognitive, MRI, and additional electroencephalography procedures. | diagnosed seizure disorder, stroke, or neurological condition; uncontrolled medical condition likely to substantially affect brain functioning (e.g., untreated thyroid condition); and head injury resulting in fractured skull or more than 30 minutes unconsciousness. Healthy controlswere also excluded for history of primary psychotic disorder or hypomania, antipsychotic medication use, current or past depressive episodes, attention-deficit/hyperactivity disorder or other learning disability, and family history of bipolar or psychotic disorder. |
| :---: | :---: | :---: | :---: | :---: |
| PHCP | USA | SCID for DSM-IV and DIGS Psychosis module performed by a trained clinical interviewer. Then all clinical materials reviewed by doctoral and graduate level psychologists to achieve a consensus diagnosis. | People with Psychosis (PwP) were between the ages of 18 and 65 years old with a diagnosis of schizophrenia, schizoaffective disorder, or bipolar I disorder with a history of psychotic symptomatology (i.e., delusions or hallucinations) with no indication that symptoms were caused by substance use or a general medical condition. While PwP were screened and excluded for current substance use issues, a history of such issues as well as current/lifetime comorbidities of any kind were permitted for enrollment in the study in order to have a sample representative of patients with psychosis in the general population while simultaneously limiting nuisance. effects. | To be eligible for enrollment, all participants spoke English as their primary language and did not have: a legal guardian (or otherwise lack capacity to provide informed consent), alcohol/drug abuse in the past month or alcohol/drug dependence in the last 6 months, a diagnosed Learning Disability or estimated IQ lower than 70 (if either condition was diagnosed based on testing by a trained professional or the latter by research staff), a current or past central nervous system disease (including: seizures, epilepsy, encephalitis, MS, Parkinson's, stroke), his- tory of head injury with skull fracture or loss of consciousness greater than 30 min , history of electro-convulsive therapy (ECT) in the last year, tardive dyskinesia (as evidenced by medical record), obstructed or com- promised vision (e.g., lazy eye that is uncorrected or was corrected after age 17 / strabismus / cross eyes / permanent eye injury / abnormality in visual field / cataract), hearing problems (e.g., cannot hear with- out hearing aid / severe tinnitus), or a condition likely making it impossibleto perform tasks (e.g., paralysis, severe arthritis). |
| RSCZ | Russian Federation | ICD-10 (F20.x) | Early or first-episode psychosis in-patients (no later than 5 years since the first episode) who were clinically stable and received antipsychotic medication therapy. Mentally healthy controls were recruited from acquaintances of the researchers and clinical staff. All participants were fluent Russian speakers, right-handed males. | Common exclusion criteria for patients and controls were: organic brain disorders, neurological or severe somatic disorders, mental retardation, alcohol or substance abuse, history of head trauma with loss of consciousness for more than 5 min . In addition, controls were excluded if they had a family history of psychiatric illness. |

| SCORE | Switzerland | ICD-10 or DSM-IV criteria | First-episode psychosis patients who <br> fulfilled criteria for brief psychotic disorder. <br> All patients were between 18 and 42 years of | History of previous psychotic disorder, psychotic symptoms secondary to an organic disorder, <br> substance abuse (except nicotine), psychotic symptoms associated with an affective psychosis or a <br> age. |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| borderline personality disorder, age younger than 18 years, inadequate knowledge of the German |  |  |  |  |
| language, and IQ less than 70 as measured by the Mehrfachwahl Wortschatz Test Form B. |  |  |  |  |

SCID: Structured Clinical Interview for DSM Disorders; CAMH: Comprehensive Assessment of Symptoms and History; MINI DSM IV: Mini-International Neuropsychiatric Interview for DSM IV; OPCRIT: Operational Criteria Checklist for Psychotic Illness and Affective Illness; DIP: Diagnostic Interview for Psychosis; ICD: international classification of disease; PANSS: Positive and Negative Syndrome Scale; MSAS: Modified Simpson-Angus Scale.

## HCP MRI data and preprocessing

HCP data were acquired on a Siemens Skyra 3T and included (i) T1-weighted images [magnetization-prepared rapid gradient echo sequence, repetition time (TR) $=2400 \mathrm{~ms}$, echo time $(T E)=2.14 \mathrm{~ms}$, field of view $(F O V)=224 \times 224 \mathrm{~mm} 2$, voxel size $=0.7 \mathrm{~mm} 3,256$ slices $]$, (ii) resting-state fMRI [gradient-echo echo-planar imaging (EPI) sequence, $\mathrm{TR}=720 \mathrm{~ms}, \mathrm{TE}=$ $33.1 \mathrm{~ms}, \mathrm{FOV}=208 \times 180 \mathrm{~mm}^{2}$, voxel size $=2 \mathrm{~mm} 3,72$ slices], and (iii) diffusion MRI (spinecho EPI sequence, $\mathrm{TR}=5520 \mathrm{~ms}, \mathrm{TE}=89.5 \mathrm{~ms}, \mathrm{FOV}=210 \times 180 \mathrm{~mm}^{2}$, voxel size $=1.25$ mm 3 , b-value $=1000 / 2000 / 3000 \mathrm{~s} / \mathrm{mm} 2$, 270 diffusion directions, 18 b 0 images). HCP data underwent the initiative's minimal preprocessing (1, 2). Resting-state fMRI data underwent distortion and head motion corrections, magnetic field bias correction, skull removal, intensity normalization, and were mapped to MNI152 space. Noise components attributed to head movement, white matter, cardiac pulsation, arterial, and large vein-related contributions were automatically removed using ICA-FIX (3). Preprocessed time series were mapped to standard gray ordinate space using a cortical ribbon-constrained volume-to-surface mapping algorithm and subsequently concatenated to form a single time series. Diffusion MRI data underwent b0 intensity normalization and correction for susceptibility distortion, eddy currents, and head motion. High-resolution functional and structural data were parcellated according to the Desikan-Killiany atlas to align with the ENIGMA-Schizophrenia dataset (3)

## Functional and structural connectivity matrix generation from HCP participants

Functional connectivity matrices were generated by computing pairwise correlations between the time series of all 68 cortical regions and between all subcortical and cortical regions; negative connections were set to zero. Subject-specific connectivity matrices were then $z$ transformed and aggregated across participants to construct a group-average functional connectome. To generate structural connectivity matrices, constrained tractography was performed using different tissue types derived from the T1w image, including cortical and subcortical gray matter, white matter, and cerebrospinal fluid (4). Multishell and multi-tissue response functions were estimated (5) and constrained spherical deconvolution and intensity normalization were performed (6, 7). The initial tractogram was generated with 40 million streamlines, with a maximum tract length of 250 and a fractional anisotropy cutoff of 0.06 . Spherical-deconvolution informed filtering of tractograms (SIFT2) was applied to reconstruct whole-brain streamlines weighted by the cross-sectional multipliers (6). To produce normative subject-specific connectivity matrices according to the Desikan-Killiany atlas, we mapped reconstructed streamlines onto the 68 cortical and 14 subcortical (including hippocampus) regions (8). Normative structural connectivity matrices were generated from preprocessed diffusion MRI data using MRtrix3 (9). The group-average normative structural connectome was defined using a distance-dependent thresholding, which preserved the edge length
distribution in individual participants (10), and was $\log$ transformed to reduce connectivity strength variance. Hence, structural connectivity was defined by the number of streamlines between two regions (i.e., fiber density). Our network centrality findings of healthy individuals reflect previously published results $(11,12)$ with centrality peaking in medial prefrontal, superior parietal and angular regions.

## ComBat batch effect adjustment

In our original mega-analytic model, regional cortical thickness and subcortical volumes were the dependent variables whilst group (SCZ, HC), age and sex were the independent variables. To show that our batch-effect correction with ComBat on the structural MRI data was successful, we performed our mega-analytical linear regression with the ComBat adjusted and unadjusted data similar with the original model, hereby adding site as an independent variable. For each region, we then computed the variance explained by site as independent variable quantified by partial $\mathrm{R}^{2}$. Partial $\mathrm{R}^{2}$ was computed using the $r$ sq.partial function of the $r s q$ library in R . It can be seen on Table S 4 that data adjustment with ComBat eliminates any variance explained by site as an independent variable, i.e., variation of imaging data due to site differences.

Table S4 ComBat batch effect adjustment confirmation

| Brain region | partial $R^{2}$ of site on ComBatadjusted data |  | partial $\mathbf{R}^{\mathbf{2}}$ of site on ComBat unadjusted data |  |

## Mega-analysis robustness and sensitivity analyses

## Reproducibility of cortical hub vulnerability across different centrality metrics

To show that cortical hub vulnerability was reproducible across multiple network metrics of centrality, besides hub strength (degree centrality) we calculated the betweenness, eigenvector and closeness centralities of the $68 \times 68$ parcellated functional and structural cortical connectivity matrices of the HCP using R package "NetworkToolbox". All centrality metrics show a high degree of intercorrelation, (mean $\pm$ SD: $\mathrm{r}_{\text {func }}=0.69 \pm 0.31, \mathrm{r}_{\text {struc }}=0.9 \pm 0.08$, Table S9). The high intercorrelation is somewhat expected, given that different aspects of the same underlying construct are measured. Similar to our main analysis using hub strength (degree centrality) (see main methods hub vulnerability model section), we examined the correlation between the cortical alteration map of SCZ with the betweenness, eigenvector and closeness centrality of each region. Correlations between SCZ-related cortical alterations and the additional centrality measures revealed very similar results as observed with hub strength (degree centrality) (Table S11).

Table S10. Correlation matrix of centrality measures

|  | Functional Connectivity |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
|  | Strength | Eigenvector | Betweenness | Closeness |
| Strength | 1 | 1 | 0.41 | 0.98 |
| Eigenvector | 1 | 1 | 0.35 | 0.96 |
| Betweenness | 0.41 | 0.35 | 1 | 0.48 |
| Closeness | 0.98 | 0.96 | 0.48 | 1 |
|  |  | Structural Connectivity |  |  |
|  | Strength | Eigenvector | Betweenness | Closeness |
| Strength | 1 | 0.98 | 0.86 | 0.92 |
| Eigenvector | 0.98 | 1 | 0.83 | 0.95 |
| Betweenness | 0.86 | 0.83 | 1 | 0.79 |
| Closeness | 0.92 | 0.95 | 0.79 | 1 |

Table S11. Cortical hub vulnerability using different centrality metrics

| Hub vulnerability | Centrality | Strength |  | Eigenvector |  | Betweenness |  | Closeness |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | R | $\mathrm{p}_{\text {spin }}$ | R | $\mathrm{p}_{\text {spin }}$ | R | $\mathrm{p}_{\text {spin }}$ | R | $\mathrm{p}_{\text {spin }}$ |
| Connectivity | Functional | 0.58 | $<0.0001$ | 0.54 | 0.0001 | 0.43 | $<0.0001$ | 0.63 | $<0.0001$ |
|  | Structural | 0.32 | 0.02 | 0.26 | 0.04 | 0.36 | 0.01 | 0.27 | 0.04 |

## Reproducibility across HCP age-matched and age-divergent ENIGMA SCZ samples

To show the robustness of our findings to the mean age group discrepancy of the multisite ENIGMA SCZ sample and the HCP sample, we split the ENIGMA SCZ sample into HCP agematched groups and age-divergent groups. We first used the HCP mean age plus/minus 1SD to define an HCP age-matched ENIGMA SCZ sample ( $\mathrm{N}=1222$, 495 SCZ ) and an age-divergent group ( $\mathrm{N}=4084,1944 \mathrm{SCZ}$ ). To show that the findings are robust across various definitions of
age-matched groups, we also used the HCP mean age plus/minus 2SDs to define the HCP agematched ENIGMA SCZ sample ( $\mathrm{N}=2651,1119 \mathrm{SCZ}$ ) and an age-divergent groups $(\mathrm{N}=2655$, $\mathrm{N}=1320 \mathrm{SCZ}$ ). Regarding the matching to the HCP sample by age mean $\pm 1$ SD, we observed a very high agreement between the resulting t -values $\left(\mathrm{r}=0.97, \mathrm{p}<2.2 \mathrm{e}^{-16}\right)$, and functional $(\mathrm{r}=$ $\left.0.92, \mathrm{p}<2.2 \mathrm{e}^{-16}\right)$ and structural ( $\mathrm{r}=0.98, \mathrm{p}<2.2 \mathrm{e}^{-16}$ ) epicenters. We are also able to confirm our finding for the hub vulnerability of functional $\left(r=0.49, \mathrm{p}_{\text {spin }}=2 \mathrm{e}^{-05}\right)$ and structural nodes $(\mathrm{r}=$ $0.26, \mathrm{p}_{\text {spin }}=0.027$ ). We find similar results when matching the sample by age using the mean $\pm$ 2 SD, observing an even higher agreement between the resulting t -values $\left(\mathrm{r}=0.97, \mathrm{p}<2.2 \mathrm{e}^{-16}\right)$, and functional $\left(r=0.98, \mathrm{p}<2.2 \mathrm{e}^{-16}\right)$ and structural $\left(\mathrm{r}=0.98, \mathrm{p}<2.2 \mathrm{e}^{-16}\right)$ epicenters. We are also able to confirm our finding for the preferential vulnerability of functional ( $\mathrm{r}=0.63, \mathrm{p}=1 \mathrm{e}-08$ ) and structural nodes $(r=0.36, p=0.003)$ to cortical thickness reduction. Lastly, we tested whether our results would be replicated in the most age-dissimilar group, i.e., individuals outside of the (mean+-2SD) window of the HCP distribution. Again, we could replicate our original findings robustly, with high agreement of t -values ( $\mathrm{r}=0.96, \mathrm{p}<2.2 \mathrm{e}^{-16}$ ), and functional $\left(\mathrm{r}=0.97, \mathrm{p}<2.2 \mathrm{e}^{-16}\right)$ and structural $\left(\mathrm{r}=0.98, \mathrm{p}<2.2 \mathrm{e}^{-16}\right)$ epicenters. We are also able to confirm our finding for the preferential vulnerability of functional ( $r=0.49, p_{\text {spin }}=2 e^{-05}$ ) and structural hubs $\left(r=0.27, \mathrm{p}_{\text {spin }}=0.023\right)$.

## Robustness and site-specific confirmation analysis of morphological alterations, hub vulnerability and disease epicenter models in SCZ

## Cortical and subcortical alterations in SCZ

To examine the reproducibility of our mega-analytic findings and to make sure that our findings were not outlier-driven, we repeated our analysis within each participating site separately. One of the participating sites (GIPSI) was excluded from this site-specific analysis since this site contains data of patients only. In a first step, we computed the $t$-value map of the cortical thickness differences between patients and controls within each participating site. Site-specific schizophrenia-related cortical alterations were similar to our multisite mega-analytical findings (Fig S1a). In addition, in 21 out of 25 sites the spatial pattern of the schizophrenia-related cortical t-value map was significant correlated with the mega-analytic (multisite aggregation) cortical t -value map indicating good spatial similarity between the cortical alteration maps (Table S13).

## Hub vulnerability and epicenter mapping

We next examined within each participating site the reproducibility of our finding that more central cortical nodes tend to display higher values of cortical thickness reductions. The
positive correlation of cortical thickness reduction with functional corticocortical degree centrality was more pronounced in functional networks (mean $\pm \mathrm{SD}: \mathrm{R}=0.23 \pm 0.28$, Table S14 ) rather than structural networks (mean $\pm \mathrm{SD}: \mathrm{R}=0.15 \pm 0.14$., Table S 14 ), with 19 and 8 sites out of 25 showing statistical significance of this relationship respectively. In a final step, we examined the reproducibility of our epicenter findings, by identifying functional and structural epicenters of SCZ (see main methods for details) within each participating site. As observed in the multisite findings site-specific epicenters were most often identified in temporo-paralimbic extending to frontal brain regions (Fig S1b), with a high degree of correlation between our original map and the site-specific ones for functional, (median $\mathrm{R}=0.6$; $\mathrm{IQR}=[0.26,0.8]$, Table S 15 ) and structural epicenters (median $\mathrm{R}=0.42 ; \mathrm{IQR}=[0.25,0.55]$, Table S15)

## Subject-level cortical abnormality modeling

We next sought to examine whether our network-based models can be translated to individual schizophrenia patients' data and how they are influenced by individual clinical factors. Batchcorrected cortical thickness data of patients were first adjusted for age and sex by residualizing the effect of age and sex using a linear model. Subsequently they were z-scored relative to healthy controls to generate individualized morphological abnormality z-score maps. To test the hub vulnerability hypothesis at an individual level we descriptively compared the expected vs observed incidence of statistically significant positive correlations of nodal centrality and patient-specific morphological abnormality maps, adjusting for spatial autocorrelation using spin permutation tests. According to an alpha of 0.05 and the properties of the Gaussian distribution we define the expected incidence of statistically significant positive correlation values as 0.025 . We next sought to test the robustness of our epicenter findings at the individual patient level. We identified patient-specific structural and functional epicenter maps by iteratively correlating the connectivity profile of each brain region to each patient's morphological abnormality map as described in the epicenter mapping section. Significance
was tested for each patient-specific epicenters using spin permutation test ( $\mathrm{p}_{\text {spin }}<0.05$ ) as described in the method section in the manuscript. We finally computed the percentage of individuals for which each region was a statistically significant epicenter, correcting for multiple testing with the Bonferroni method.

## Subject-level hub vulnerability modeling

To assess whether network atrophy models can also explain individual patient data, each patient-specific cortical abnormality map was correlated with the normative degree centrality maps (Fig. S2). We observed similar associations between individual cortical maps and functional ( $\mathrm{p}_{\text {spin }}<0.05$ in $18.2 \%$ of individuals with SCZ ) as well as structural cortico-cortical hubs ( $\mathrm{p}_{\text {spin }}<0.05$ in $8.1 \%$ of individuals with SCZ) as seen in the group-level analysis. By contrast, a null distribution of $p$-values (corrected for spatial autocorrelation) would only show a rate of approximately $2,5 \%$ statistically significant positive correlations. Thus, we observed a 7.2 -fold ( $18.2 \%$ vs. $2.5 \% ; \chi^{2}$ Fun $2466.4, \mathrm{df}=1, \mathrm{p}$-value $<2.2 \mathrm{e}^{-16}$ ) and 3.2 -fold ( $8.1 \%$ vs $2.5 \%$, $\chi^{2}=315_{\mathrm{s} \cdot \mathrm{tt}} 5_{\mathrm{uc}} 8, \mathrm{df}=1, \mathrm{p}$-value $<2.2 \mathrm{e}^{-16}$ ) enrichment of significant associations between individual morphometric maps and cortical centrality maps than would be expected in the null hypothesis.

## Subject-level epicenter modeling

Using each patient's individual cortical abnormality map, we further identified patient-specific structural and functional epicenters with a marked overlap in the top significant epicenters identified by our mega-analysis. Specifically, 9 out of 10 top epicenters overlap between the individual epicenter models and our group-level mega-analysis including the entorhinal cortices, banks of superior temporal sulci, left inferior temporal gyrus, and frontal gyri (bilateral pars triangularis, left pars opercularis, right pars orbitalis) (Fig. S2). In summary, although the individual subject-level data displayed overall lower sensitivity, due to the increased heterogeneity in cortical abnormality patterns, the results closely mirrored our group-level analysis. Collectively, individual network modeling supported both the hub vulnerability hypothesis and the most significant epicenters as identified by our mega-analysis.

Figure S2. Individual-level network modeling analysis in schizophrenia. (A) Hub vulnerability. On an individual patient level, we computed patient-specific morphological abnormality maps and tested the hub vulnerability hypothesis for each patient correcting for spatial autocorrelation (pspin $<0.05$ ). The resulting R-value distributions are enriched in positive correlations (7.2-fold, $18.2 \%$ vs. $2.5 \% ; \chi^{2}$ func $=2466.4, \mathrm{df}=1, \mathrm{p}$-value $<2.2 \mathrm{e}^{-16}$ and 3.2 -fold, $8.1 \%$ vs $2.5 \%, \chi^{2}$ $=3_{\mathrm{st}} 1_{\mathrm{ru}} 5_{\mathrm{c}} .58, \mathrm{df}=1, \mathrm{p}$-value $<2.2 \mathrm{e}^{-16}$ ). (B) Epicenter Mapping. On an individual patient level, we computed patient-specific disease epicenters by identifying regions with a connectivity profile which significantly correlated ( $\mathrm{p}_{\text {spin }}<0.05$ ) with each patient's morphological abnormality map. Epicenter map depicts the percentage of individual patients for whom each region is a significant functional (above) or structural (below) epicenter. The ranking of regions most highly enriched for statistical significance in individuals correlates highly with the original epicenter map.

## Subject-level correlation of clinical variables to hub vulnerability and epicenters

Having established both network-based models in subject-level data (see results above), we next examined the association between individual clinical factors and patient's hub vulnerability and epicenters respectively. To this end, we correlated the subject-level hub vulnerability scores with antipsychotic medication, duration of illness, PANSS total, PANSS positive, negative and general scores (Table S16). To examine the relationship between individual subject-level epicenters and clinical factors, we correlated each patient's epicenters (based on significance) with the above-mentioned clinical factors. To control for multiple comparisons $p$-values were adjusted within each clinical variable analysis using the Bonferroni method. (Tables S17-18).

Table S16. Correlations between subject-level functional and structural hub vulnerability and clinical scores

Individual Hub Vulnerability

|  | Functional Connectivity |  | Structural Connectivity |  |
| :--- | :--- | :--- | :--- | :--- |
| Clinical Variables | R | pval (Bonferroni) | R | pval (Bonferroni) |
| PANSS Positive | 0.06 | 0.027 | 0.06 | 0.025 |
| PANSS Negative | 0.03 | 0.241 | 0.05 | 0.018 |
| PANSS General | 0.21 | $<0.0001$ | 0.13 | 0.01 |
| PANSS Total | 0.1 | 0.001 | 0.09 | 0.004 |
| Chlorpromazine | -0.02 | 0.403 | -0.01 | 0.832 |
| Duration of Illness | -0.04 | 0.112 | 0.02 | 0.309 |
| All p-values are corrected for multiple comparison using the Bonferroni method |  |  |  |  |

## Subject-level robustness and sensitivity analysis

To show the robustness of the correlation values between clinical variables and our individual-level hub vulnerability and epicenter findings we performed a sensitivity permutation analysis in our sample. Specifically, we generated 100 different permutations of $80 \%$ of our sample- i.e., an $80-20$ split without resampling. We accordingly repeated the correlation analysis with the clinical variables 100 times. Our results show that the original findings are highly robust to perturbation of our sample (Fig S3-9).

Figure S3. Robustness-Permutation analysis of stability of correlation of hub vulnerability at the individual level to individual clinical symptoms. Violin plots represent the distribution of values of the 100 permutations using a different $80 \%$ of the sample. Central dot represents the value obtained using $100 \%$ of our sample.

## Cross-modality generalizability of hub vulnerability and epicenter models in surface area alterations of schizophrenia

Most research on cortical hub vulnerability and epicenter models of brain alterations to date has focused on cortical thickness or gray matter volume. Cortical surface area has a heritability of a magnitude similar to cortical thickness, while both are characterized by distinct genetic underpinnings $(13,14)$. In line with this, the radial hypothesis proposes distinct developmental mechanisms for cortical thickness and surface area. It suggests that cortical thickness results from the neurogenetic division of neural progenitor cells, whereas the expansion of surface area is associated with the propagation of these cells (15). Here we applied our network models to schizophrenia-related cortical surface alterations to test whether the hub vulnerability and epicenters found for cortical thickness alterations are generalizable across both modalities. Thus, these complementary analyses will enable us to identify shared and distinct network mechanisms associated with either one or both cortical measures in schizophrenia. To this end we expanded our original analysis to thoroughly examine the relationship of the normative functional and structural brain networks with surface area alterations in schizophrenia.

## Surface area mega-analysis

Using linear models controlling for age and sex across our entire mega-analytic sample ( $\mathrm{n}=2,439 \mathrm{SCZ}$, $\mathrm{n}=2,867 \mathrm{HC}$ ), we observed widespread cortical surface area alteration patterns in people with SCZ relative to HC . The derived case-control mega-analytical t -value map closely mirrored the meta-analytic cohen's d effect sizes previously reported by can Erp and colleagues (Fig. S10A; r $=0.83$, $\mathrm{p}_{\text {spin }}<0.0001$ ) (16). Cortical Surface area reductions in SCZ were in accordance with previous findings (16) and generally lower in mean effect size than CT differences $\left(\mathrm{MD}_{\text {mega }}=0.14, \mathrm{CI}=[0.13,0.17] ; \mathrm{t}=15.7, \mathrm{df}=\right.$ 67, $\mathrm{p}<2.2 \mathrm{e}-16$ ). However, the spatial pattern of SCZ-related surface area and cortical thickness alteration maps were highly correlated suggesting strong regional agreement of reductions in both modalities. $\left(\mathrm{r}_{\text {mega }}=0.60, \mathrm{p}_{\text {spin }}=0.0001\right)$. Strongest surface area reductions could be seen in the bilateral fusiform, superior and rostral middle frontal, superior and middle temporal and postcentral gyri (all tvalues $>6$, FDR $p<1.57 \mathrm{E}-07$, Fig. S10A, Table S19). For results of all 68 cortical DKT regions see Table S19.

## Functional and structural degree centrality predict regional susceptibility to surface area alterations

Following our cortical thickness analysis, we tested the vulnerability of hubs to surface area reductions in SCZ and compared the spatial patterns of normative functional and structural nodal degree centrality (Fig. 2B) and SCZ-related surface area alterations (Fig. S10B). Mirroring findings from our cortical thickness analyses, a similar vulnerability of cortical hubs could be observed for surface area reductions, in functional $\left(r=0.53, \mathrm{p}_{\text {spin }}=0.0004\right)$ and a trend in the same direction for structural cortico-cortical hubs $\left(\mathrm{r}=0.22, \mathrm{p}_{\text {spin }}=0.08\right)$. In sum, functional and structural normative degree centrality predicted the susceptibility of a cortical region to the magnitude of surface area alterations.

## Disease epicenters of schizophrenia-related surface area alterations

The epicenter mapping analysis is explained in detail in the main methods section and Figure 3A. In brief, similar to our analysis with SCZ-related cortical thickness alteration, we examined whether the spatial pattern of cortical surface alterations in SCZ are associated with the cortical connection of one or more brain regions to all other cortical regions. A significant relationship between the cortico-cortical connectivity profiles of a region and the pattern of SCZ-related surface alterations suggests that this region could be an epicenter. Such a region might influence the spread of alterations across the cortex in a network-like manner. To identify those regions that might be most likely epicenters, we systematically correlated the normative functional and structural cortico-cortical connectivity profile of each region with the whole-brain patterns of surface area alterations in SCZ (Fig. 3A). Regions were then ranked in descending order based on the strength of their correlation coefficients, with the highestranked regions being considered the most significant disease epicenters. The epicenter findings for surface area alterations were very similar to those observed for cortical thickness alterations in SCZ with temporo-paralimbic and frontal regions emerging as the most significant epicenters (Fig. S10C, Table S20). Specifically, the entorhinal cortices, banks of superior temporal sulci, inferior temporal, and additionally frontal gyri (bilateral pars triangularis, left pars opercularis) ranked highest as functional epicenters. For structural epicenters, the right inferior parietal cortex and pars triangularis of the inferior frontal gyrus emerged as significant epicenters of SCZ-related surface area alteration (Fig S 10 C ). In addition, the overall pattern of functional and structural epicenters for surface area alterations correlated highly with the epicenter maps of cortical thickness alteration ( $\mathrm{r}_{\text {func }}=0.93, \mathrm{p}_{\text {spin }}<0.0001, \mathrm{r}_{\text {struc }}$ $=0.85, \mathrm{p}_{\text {spin }}<0.0001$ ) confirming the high similarity of epicenters across both cortical measures.

## A. Mega-analysis of surface area abnormalities in schizophrenia

B. Nodal Stress hypothesis in schizophrenia

C. Epicenter mapping of surface area abnormalities in schizophrenia

Figure S10. Cross-modality generalizability of mega- and network modelling analysis in surface area.
(A) Mega-analytical unthresholded $t$-maps of cortical surface area alterations in $\operatorname{SCZ}(\mathrm{n}=2,439)$, compared to HC ( $\mathrm{n}=2,867$ ). (B) Correlation of cortical surface area alterations with node-level functional (left) and structural (right) maps of degree centrality. Similar to our cortical thickness findings in SCZ, regions with high functional or structural centrality are significantly more likely to display surface area alterations in the cortex. (C) Correlation coefficient maps depicting the strength of association between the normative region-based functional (left) and structural (right) connectivity and the SCZ-specific morphological abnormality maps. Disease epicenters are regions more strongly connected with regions showing significant surface area alterations - and, inversely, more weakly connected with regions with less pronounced surface area alterations. Asterisks denote the top five significant epicenters. Top-5 functional epicenters, cortical: (R): lateral orbitofrontal cortex, caudal middle frontal gyrus, middle temporal gyrus (L): caudal middle frontal gyrus, pars opercularis of inferior frontal gyrus. Top-2 structural epicenters: (R): inferior parietal cortex, pars triangularis of inferior frontal gyrus.

Table S19. Surface area differences between schizophrenia patients and healthy controls

| Regions | T-values | $p$ values (Bonferronicorrected) | Cohen's D | $\begin{aligned} & \text { Cohen's D } \\ & 95 \% \text { CI } \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: |

## Subject-level correlations individual hub vulnerability and epicenters of surface area alterations

## Subject-level hub vulnerability and clinical variables

Individual R values of cortical hub vulnerability to surface area alterations were, similar to the corresponding hub vulnerability indices for cortical thickness alterations, consistently associated with PANSS general symptom score ( $\mathrm{r}_{\text {func }}=0.14, \mathrm{p}_{\text {Bonf }}=0.033, \mathrm{r}_{\text {struc }}=0.19, \mathrm{p}_{\text {Bonf }}=0.001, \mathrm{df}=383$ ) and PANSS total score $\left(\mathrm{r}_{\text {func }}=0.08, \mathrm{p}_{\text {Bonf }}=0.065, \mathrm{r}_{\text {struc }}=0.09, \mathrm{p}_{\text {Bonf }}=0.026, \mathrm{df}=1039\right.$ ). Robustness of these results were confirmed by running 100 permutations with $80 \%$ of the sample each time without resampling (Fig S11, Table S21).

Figure S11. Stability of correlation of hub vulnerability and clinical variables at the individual level. Robustness-Permutation analysis of stability of correlation of hub vulnerability to surface area alterations at the individual level and individual clinical symptoms. Violin plots represent the distribution of values of the 100 permutations using a different $80 \%$ of the sample. Central dot represents the value obtained using $100 \%$ of our sample.

Table S21. Correlations between subject-level functional and structural hub vulnerability and clinical scores

| Individual Hub Vulnerability | Functional Connectivity |  | Structural Connectivity |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
|  | R | pval (Bonferroni) | R | pval (Bonferroni) |
| Clinical Variables | 0.07 | 0.027 | 0.07 | 0.021 |
| PANSS Positive | 0.04 | 0.586 | 0.06 | 0.063 |
| PANSS Negative | 0.14 | 0.033 | 0.19 | 0.001 |
| PANSS General | 0.08 | 0.065 | 0.09 | 0.026 |
| PANSS Total | 0.02 | 1 | 0.03 | 1 |
| Chlorpromazine | -0.01 | 1 | 0.01 | 1 |
| Duration of Illness |  |  |  |  |
| All p-values are corrected for multiple comparison using the Bonferroni method |  |  |  |  |

## Subject-level epicenters and clinical variables

With respect to the correlation between subject-level epicenters and clinical scores, we also found convergent results using individual epicenters cortical thickness and surface area alterations. For both, cortical thickness and surface area, we found significant correlations between the individual epicenter likelihood and higher PANSS general scores (Table S22\&S23). Regarding individual functional epicenters, 29 of 68 functional cortical thickness epicenters and 13 surface area epicenters were significantly correlated with higher PANSS general scores (Table S21). 10 of the 13 identified surface area epicenters overlapped with the 29 cortical thickness epicenters suggesting a strong overlap between the association of individual epicenters and symptom scores. To evaluate the statistical significance of the overlap between the sets of significant results between PANSS general symptom scores and higher cortical thickness and surface area epicenter likelihood respectively, we performed a hypergeometric test $\left(\mathrm{N}_{\text {total }}=68, \mathrm{~N} 1=29, \mathrm{~N} 2=13, \mathrm{~N}_{\text {overlap }}=10 ; \mathrm{p}=0.007\right)$. The overlap of 10 significant results between the two sets is therefore statistically significant, suggesting common neuroanatomical substrates in terms of cortical thickness and surface area regarding their correlation with general symptomatology in schizophrenia. In addition to these significant correlations with functional surface area epicenters, significant correlation between 16 of 68 structural surface area epicenters also correlated significantly with higher PANSS general symptom scores. Together, these findings suggest that individual functional and structural epicenters of surface area are related to higher PANSS general symptomatology.

Table S22. Correlations between individual subject-level functional surface area epicenters and clinical scores

| Functional connectivity |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Cross-disorder comparison of hub vulnerability and epicenter mapping

Similar to our cortical thickness analysis, we further probed whether our hub and epicenter findings for surface area alterations in SCZ are specific or represent associations that are shared across the schizophrenia-affective disorder spectrum. To this end, we leveraged the metaanalytic cortical surface area case-control maps of bipolar disorder (BD) and major depressive disorder (MDD) (17, 18). Convergent with our cortical thickness findings, surface area alterations in BD were moderately correlated with cortico-cortical hubs ( $\mathrm{r}_{\text {func }}=0.3, \mathrm{p}_{\text {spin }}=0.054$; $r_{\text {struc }}=0.2, p_{\text {spin }}=0.15$ ) while no associations were found in MDD (all $p_{\text {spin }}>0.05$ ) (Fig. S12A). These findings confirm our hub vulnerability models of cortical thickness alterations showing significant hub vulnerability for surface area alterations in SCZ and BD but not MDD. In accordance with our cortical thickness analysis, the left caudal middle frontal gyrus emerged as significant disease epicenter of surface area alterations in BD , whereas no significant epicenters were observed for surface are alterations in MDD (Fig. S12B). These findings mirror our original cross-disorder comparison with cortical thickness alterations showing that the magnitude of observed cortical disease epicenters was most pronounced in SCZ, intermediate in BD and relatively lacking in MDD

Figure S12. Cross-disorder comparison of network modeling of cortical surface area alterations. (A) Correlation of disorder-related surface area alterations to node-level functional (left) and structural (right) maps of degree centrality in BD and MDD. Convergent with our cortical thickness analysis, in BD , cortical regions with high structural centrality are significantly more likely to display higher surface area alterations. No such relationship is observed in MDD. (B) Correlation coefficient maps depicting strength of association between each region normative functional (top) and structural (bottom) connectivity and the BD-specific surface area alteration map (left) and the MDD-specific surface area alteration map (right). Asterisks denote the top five significant epicenters. Functional epicenters in BD: Left caudal middle frontal gyrus. No significant epicenters could be detected in MDD.

## Acknowledgments per dataset

Acknowledgments per dataset are as follows:
ASRB: The Australian Schizophrenia Research Bank (ASRB), was supported by the National Health and Medical Research Council of Australia (NHMRC) (Enabling Grant, ID 386500), the Pratt Foundation, Ramsay Health Care, the Viertel Charitable Foundation and the Schizophrenia Research Institute. Chief Investigators for ASRB were Carr, V., Schall, U., Scott, R., Jablensky, A., Mowry, B., Michie, P., Catts, S., Henskens, F., Pantelis, C. We thank Loughland, C., the ASRB Manager, and acknowledge the help of Jason Bridge with ASRB database queries. CP was supported by NHMRC Senior Principal Research Fellowships (IDs: 628386 \& 1105825); GC was supported by the Schizophrenia Research Institute utilizing infrastructure funding from the New South Wales Ministry of Health and New South Wales Ministry of Trade and Investment (Australia); JF was supported by NHMRC project grant (1063960); MG was supported by NHMRC as an R.D. Wright Biomedical Career Development Fellow (1061875). MJC was supported by NHMRC Senior Research Fellowship (1121474). CSW is funded by the NSW Ministry of Health, Office of Health and Medical Research. CSW is a recipient of a National Health and Medical Research Council (Australia) Principal Research Fellowship (PRF) (\#1117079).

CAMH: The CAMH datasets were collected and shared with support from the CAMH Foundation and the Canadian Institutes of Health Research.

CIAM: The CIAM study is supported by the South African Medical Research Council and National Research Foundation of South Africa.

COBRE: The COBRE dataset and investigators were supported by NIH grants R01EB006841 \& P20GM103472, as well as NSF grant 1539067. JT (senior author) and VDC are supported by 5R01MH094524. JMS is supported by R01 AA021771 and P50 AA022534.

ESO: The ESO study was funded by NPU I - LO1611 and Ministry of Health, Czech Republic - Conceptual Development of Research Organization 00023001 (IKEM).

FIDMAG: Supported by Instituto de Salud Carlos III (Co-funded by European Regional Development Fund/European Social Fund) "Investing in your future"): Miguel Servet Research Contract (CPII16/00018 to E. Pomarol-Clotet and CP14/00041 to J. Radua.).

FOR2107 Marburg: This work was funded by the German Research Foundation (DFG), Tilo Kircher (speaker FOR2107; DFG grant numbers KI 588/14-1, KI 588/14-2), Axel Krug (KR 3822/5-1, KR 3822/7-2), Igor Nenadic (NE 2254/1-2), Carsten Konrad (KO 4291/3-1).

FOR2107 Muenster: The FOR2107 Muenster study was funded by the German Research Foundation (DFG, grant FOR2107 DA1151/5-1 and DA1151/5-2 to UD) and the Interdisciplinary Center for Clinical Research (IZKF) of the medical faculty of Münster (grant Dan3/012/17 to UD).

FSL_Rome: This study was supported by grants (RC10-11-12-13-14-15/A) from the Italian Ministry of Health and by the ERANET NEURON from the European Commission.

MPRC: Support was received from NIH grants U01MH108148, 2R01EB015611, R01MH112180, R01DA027680, R01MH085646, P50MH103222 and T32MH067533, a state of Maryland contract (M00B6400091) and NSF grant (1620457).

OLIN: The Olin study was supported by NIH grants R37MH43375 and R01MH074797.
PAFIP: The PAFIP study was supported by Instituto de Salud Carlos III, MINECOSAF2013-46292-R, PSYSCAN (Exp.: HEALTH.2013.2.2.1-2_Grant agreement no. 603196), FIS PI14/00639. We want to particularly acknowledge the patients and the BioBankValdecilla
(PT13/0010/0024) integrated in the Spanish National Biobanks Network for its collaboration. We thank IDIVAL Neuroimaging Unit for its help in the technical execution of this work.

PENS: This work was supported by the awards by the Department of Veterans Affairs Clinical Science Research and Development Service (Grant No. I01CX000227 [to SRS]) and the National Institute of Mental Health of the National Institutes of Health (NIH) (Grant No. R01MH1 12583 [to SRS]). Thiswork is also supported by the National Institute of Neurological Disorders and Stroke of the NIH (Grant No. P30 NS076408), the National Eye Institute of the NIH (Grant No. P30 EY011374), the National Institute of Biomedical Imaging and Bioengineering of the NIH (Grant No. P41EB015894), and the NIH (Grant No. 1S10OD017974-01). The content is solely the responsibility of the authors and does not necessarily represent the official views of the Department of Veterans Affairs or the NIH.

PHCP: This work was supported by the National Institutes of Health (U01MH108150) and the Center for Magnetic Resonance Research (P41 EB027061; 1S10OD017974).

SCORE: This study was supported in part by grant 3232BO_119382 from the Swiss National Science Foundation. We thank the FePsy (Frueherkennung von Psychosen; early detection of psychosis) Study Group from the University of Basel, Department of Psychiatry, Switzerland, for the recruitment of the study participants. The FePsy Study was supported in part by grant No. SNF $3200^{-05} 7216 / 1$, ext./2, ext./3.

Singapore: This work was supported by research grants from the National Healthcare Group, Singapore, and the Singapore Bioimaging Consortium research grants awarded to K.S.

SWIFT: This research was supported in part by the Swiss National Science Foundation (grant no. 320030_146789).

UCISZ: The UCISZ study was supported by the National Institutes of Mental Health grant number R21MH097196 to TGMvE. UCISZ data was processed by the UCI High Performance Computing cluster supported by Joseph Farran, Harry Mangalam, and Adam Brenner and the National Center for Research Resources and the National Center for Advancing Translational Sciences, National Institutes of Health, through Grant UL1 TR000153. AB was also supported by NIH grants 5R01 MH61603, and 2R01MH058251; JF by NIMH (R01 MH-58262).

UPENN: The UPENN study was supported by National Institute of Mental Health grants MH064045, MH60722, MH019112, MH085096 (DHW), and R01MH10770 (TDS).

Zurich: This study was supported by the Swiss National Science Foundation (Grant No. 105314_140351 to SK, Grant No. P2SKP3_178175 to MK).
