**NMR analysis of ligand 7b:** NMR analysis indicates that ligand **7b** is  $C_3$  symmetric at 298 K. It was not possible to assign C9, presumably because it is overlapping with C10, C11 or C12 and does not show a cross peak in the  $^1\text{H}$ - $^{13}\text{C}$  HMBC NMR spectrum.

**NMR analysis of ligand 7e:** At lower temperature, ligand **7e** is a mixture of a  $C_3$  symmetric and a  $C_S$  symmetric rotamer (see  $^{29}\text{Si}$  NMR spectrum at 233 K). However, at higher temperature (353 K) the rotamers are averaged on the NMR timescale and a simpler NMR dataset was obtained. Therefore the assignments are based on the spectra recorded at 353 K.

**NMR analysis of complex 3a:**  $^1\text{H}$  NMR signals of complex **3a** were broad at 298 K. The complex was characterized at 333 K where all the signals were sharper (see VT NMR data). The analysis indicates that the complex is  $C_3$  symmetric at this temperature. The  $^{95}\text{Mo}$  NMR shift was extracted after peak fitting and measured at 298 K.

**NMR analysis of complex 3d:** The two methyl groups C10 and C11 are diastereotopic. H5 and H6 form a complex multiplet. It was difficult to extract their exact chemical shift. Therefore, the average shifts of the multiplet are given. The signal of C5 is overlapping with one of the solvent peaks. The shift was verified via  $^{13}\text{C}$  DEPT-135 NMR and  $^1\text{H}$ - $^{13}\text{C}$  HSQC NMR experiments.  $^{14}\text{N}$  NMR data was measured 333 K and the shift was extracted after peak fitting.

**NMR analysis of complex 13a:** The lateral phenyl groups are diastereotopic; one of them has an increased rotational barrier. This is also true for the nitrogen-aryl bond of the amide ligands (please see the  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra at different temperatures). The tripodal ligand framework itself is  $C_3$ -symmetric. Multiple atoms have rather unusual chemical shifts, likely due to the paramagnetic nature of the complex. Generally, the closer they are located to the Mo–N–Mo moiety, the stronger the paramagnetic shift. In some cases no HMBC cross peaks were observed, but  $^{13}\text{C}$  assignments were done by high temperature 2D NMR data. However, the shift of C13 could not be confirmed with 2D NMR data and was only observed in the 1D  $^{13}\text{C}$  NMR spectrum. Due to the high sensitivity of this complex,  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra always showed small amounts of free aniline  $\text{HN}(t\text{Bu})\text{Ar}$  and the terminal nitrido complex  $[\text{N} \equiv \text{Mo}(\text{N}(t\text{Bu})\text{Ar})_3]$  (**10**) ( $\text{Ar} = 3,5\text{-dimethylphenyl}$ ).

### NMR analysis of complex **13b**:

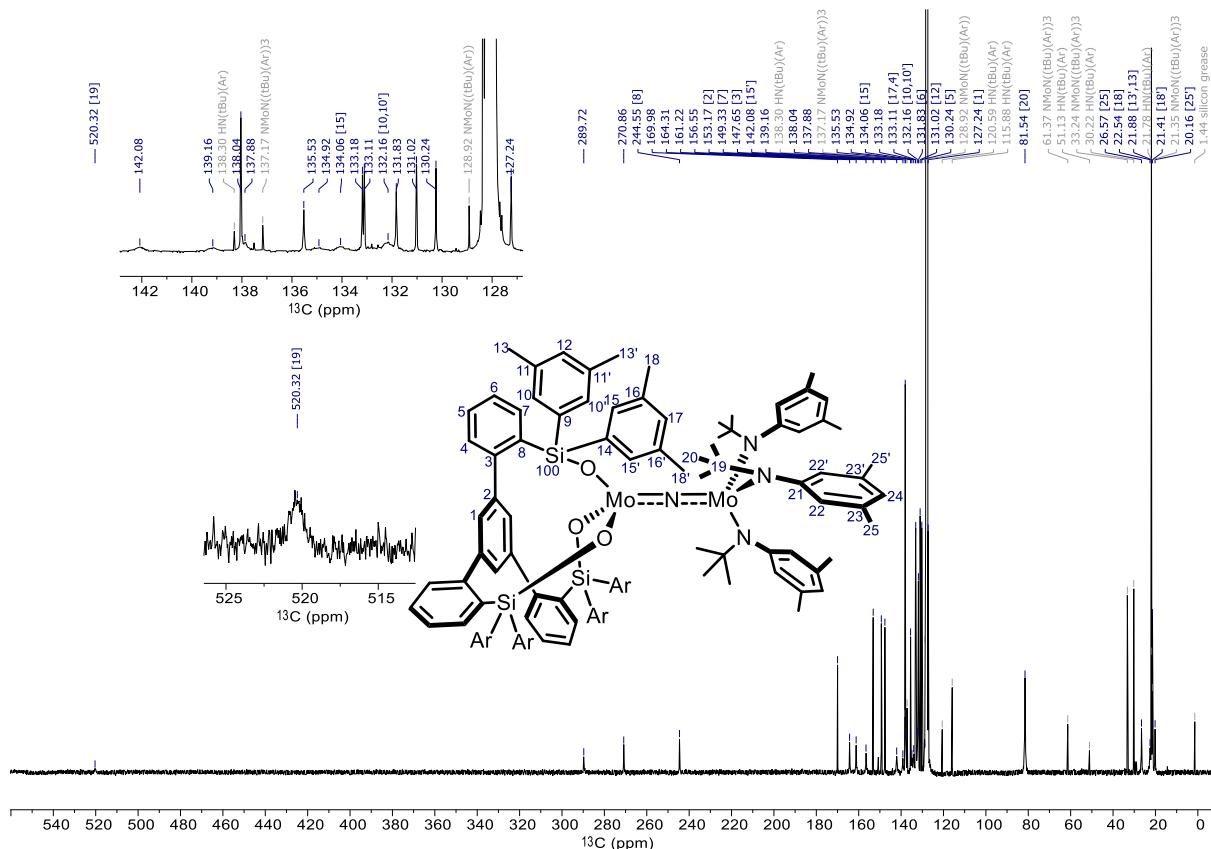

Most of the characteristic signals of the tripodal ligand backbone could be assigned. Si100 and C8 show a strong paramagnetic chemical shift compared to the normal chemical shift range. H1 is strongly shifted in the <sup>1</sup>H NMR spectrum. The signals of the amide ligands also show a rather large temperature dependence (see VT data), which is typical for paramagnetic species. Additionally, the signals are broadened due to a hindered rotation of the nitrogen-aryl-bond. The lateral aryl groups (H10, H10', H12, H13, H13' and H15; H15', H17, H18, H18') are diastereotopic. Additionally, the signals of these aryl groups are broadened due to a hindered rotation around the silicon-aryl-bond. Because of the paramagnetism and the hindered rotation a full assignment of all signals was not possible. Due to the high sensitivity of complex **13b**, <sup>1</sup>H and <sup>13</sup>C NMR spectra showed small amounts of free aniline HN(*t*Bu)(Ar) and terminal nitrido complex [N≡Mo(N(*t*Bu)(Ar))<sub>3</sub>] (**10**) (Ar = 3,5-dimethylphenyl).
