

Soil community history strengthens belowground multitrophic functioning across plant diversity levels in grassland experiment

SUPPLEMENTARY INFORMATION

Supplementary Note 1

Probability of prey consumption based on predator-prey mass ratio

We have used the model proposed by (1):

$$P_{ij} = \theta_i \exp\left(-\frac{(m_i - m_j - \mu_i)^2}{2\sigma_i^2}\right) \quad (1)$$

$$\mu_i(m_i) = \beta_{\mu 0} + \beta_{\mu 1} m_i \quad (2)$$

$$\sigma_i^2(m_i) = \exp(\beta_{\sigma^2 0} + \beta_{\sigma^2 1} m_i) \quad (3)$$

$$\theta_i(m_i) = \frac{\exp(\beta_{\theta 0} + \beta_{\theta 1} m_i)}{1 + \exp(\beta_{\theta 0} + \beta_{\theta 1} m_i)} \quad (4)$$

Where P_{ij} is the probability that predator i consumes prey j , m_i and m_j are their $\log_{10}(g)$ body-masses, μ_i is the optimal \log_{10} size ratio for predator i , θ_i is the feeding probability when prey j matches the optimal size ratio. The coefficients (Table S1) were re-estimated after restricting the data used in (1) to invertebrate-invertebrate interactions in terrestrial food webs.

Table S1. The coefficients of the model

	mean	2.50% CrI	97.50% CrI
$\beta_{\mu 0}$	0.35	0.3453	0.3548
$\beta_{\mu 1}$	-0.2235	-0.2278	-0.2192
$\beta_{\sigma^2 0}$	-0.1167	-0.1225	-0.111
$\beta_{\sigma^2 1}$	-0.0106	-0.0161	-0.0049
$\beta_{\theta 0}$	0.3742	0.3698	0.3784
$\beta_{\theta 1}$	0.0105	0.060	0.0150

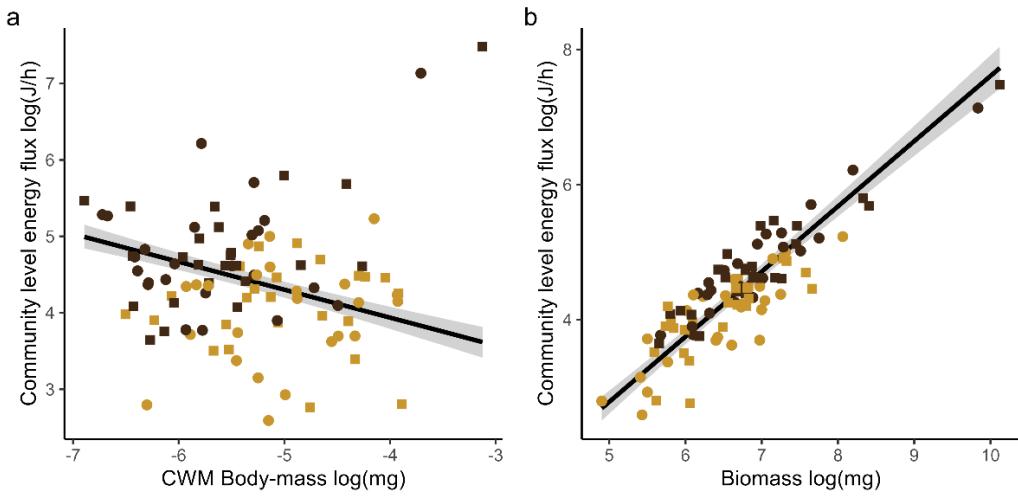

Figure S1 Marginal effects of community weighted mean body-mass and biomass on community level energy flux. These relationships explain why the observed differences in average body-mass and fauna community body-mass shown in Fig. 3 of the main text give rise to the difference in energy flux shown in Fig 1b. Color differentiates soil history treatments: community specific soil (brown), unrelated soil (yellow). Shape differentiates plant history treatments: community specific plant history (square), unrelated (circle). Solid lines are mean estimates for the average relationship bound by 95% uncertainty intervals. In both panels n=96.

Table S2 Sensitivity of main findings to the method of body-mass estimation. For our main analysis, fluxes, fauna community biomasses and cwm body-masses were calculated based on mesocosm specific macro and mesofauna taxa body-mass information. Here we contrast the results of that analysis to ones produced based on the average across mesocosms body-mass of each taxon, i.e. ignoring body - mass differences across mesocosms. The top half of the table repeats the estimates and credible intervals reported in the main text. The bottom half shows the respective estimates and intervals for the reanalysis.

main analysis – mesocosm specific body-mass					
response	contrast	mean	lower	upper	
total flux	with – without soil history	0.71	0.44	0.98	
predation	with – without soil history	0.6	0.3	0.93	
herbivory	with – without soil history	0.96	0.53	1.39	
microbivory	with – without soil history	0.59	0.4	0.79	
detritivory	with soil, no plant history – without soil history	-0.83	-1.22	-0.46	
detritivory	with soil, no plant history – with soil and plant history	-0.44	-0.87	-0.01	
fauna biomass	with – without soil history	0.41	0.13	0.71	
cwm body-mass	with – without soil history	-0.64	-0.94	-0.36	
reanalysis – across mesocosms body-mass					
response	contrast	mean	lower	upper	
total flux	with – without soil history	0.7	0.44	0.96	
predation	with – without soil history	0.54	0.24	0.86	
herbivory	with – without soil history	0.95	0.54	1.39	
microbivory	with – without soil history	0.58	0.40	0.78	
detritivory	with soil, no plant history – without soil history	-0.88	-1.31	-0.44	
detritivory	with soil, no plant history – with soil and plant history	-0.51	-0.94	-0.09	
fauna biomass	with – without soil history	0.40	0.13	0.68	
cwm body-mass	with – without soil history	-0.65	-0.94	-0.36	

Supplementary Note 2

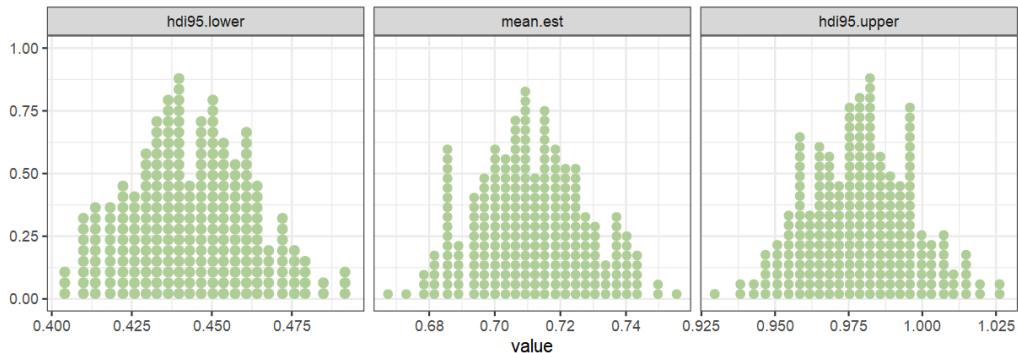

Analysis of sensitivity of main findings to variation of community properties

We examined the sensitivity of our main findings to variations of biomass and metabolic losses. To do so, we perturbed two fundamental properties of the observed communities. First, we randomly sampled abundance of the taxa in each community from the interval [$\text{abundance}_{\text{obs}} - 0.2 * \text{abundance}_{\text{obs}}$, $\text{abundance}_{\text{obs}} + 0.2 * \text{abundance}_{\text{obs}}$]. Perturbations of abundance result in perturbations of biomass ($\text{biomass} = \text{abundance} * \text{body-mass}$), which itself feeds into the interaction matrix (as predatory interactions depend on the relative biomass of prey taxa). They also result in perturbations of population-level metabolic losses ($\text{Loss}_{\text{pop}} = \text{Loss}_{\text{ind}} * \text{abundance}$). We additionally perturbed individual metabolic losses by drawing from the interval [$\text{Loss}_{\text{ind}} - 0.2 * \text{Loss}_{\text{ind}}$, $\text{Loss}_{\text{ind}} + 0.2 * \text{Loss}_{\text{ind}}$]. This variation in the population-level loss term permits to relax the equilibrium assumption, by adding a new component to the loss term that is equivalent to a change in biomass per unit of time. For consumer i , the energy gains (G_i) through consumption and assimilation efficiency, are balanced by losses through predation (P_i) and metabolism (L_i) as well as an extra term representing an additional loss or gain of energy (ΔL_i) which can represent changes in species (because of the direct relationship between joules and biomass):

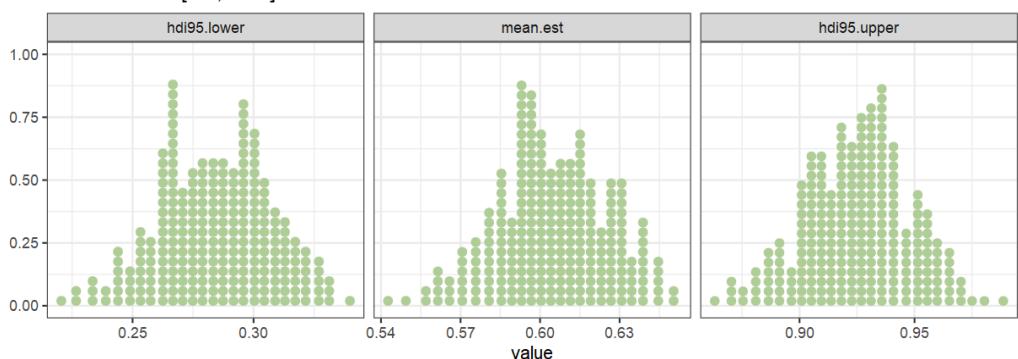

$$G_i = P_i + L_i + \Delta L_i \quad (5)$$

Using this approach, we generated 250 versions of our communities or in other words, 250 versions of the experimental data. We then repeated our analysis for each of the 250 versions. Here we report on the variation of mean estimates and credible intervals of the results reported in the main text.

Total flux - mean difference of soil treatments
main text: 0.71 [0.44, 0.98]

Predation flux - mean difference of soil treatments
main text: 0.6 [0.3, 0.93]

Herbivory flux - mean difference of soil treatments
main text: 0.96 [0.53, 1.39]

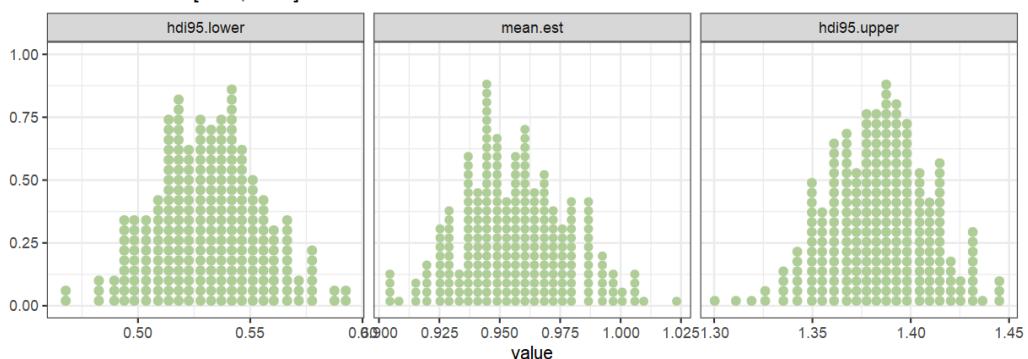

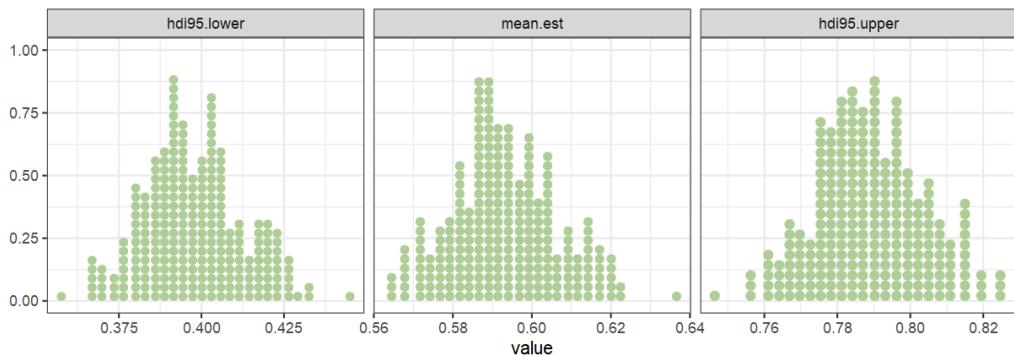

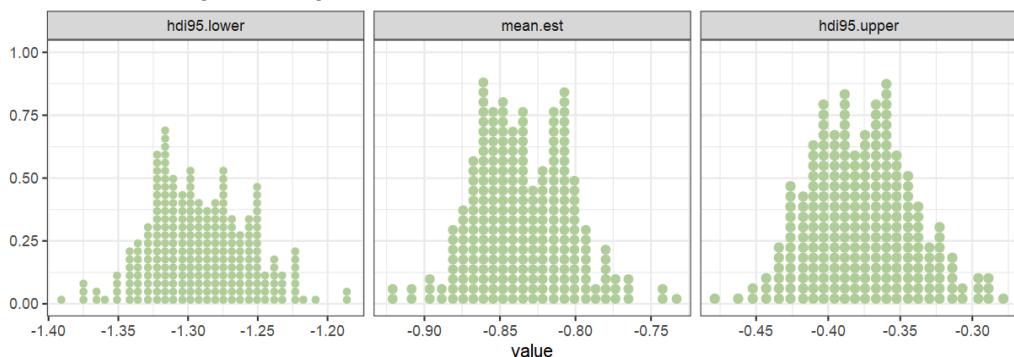

Figure S2 Variation of the mean estimate and lower and upper bounds of the credible interval of differences between history treatments, across the 250 versions (each dot corresponds to one version). Above each set of figures is shown the estimate reported in the main text. Red color highlights those instances where the credible interval contains zero.

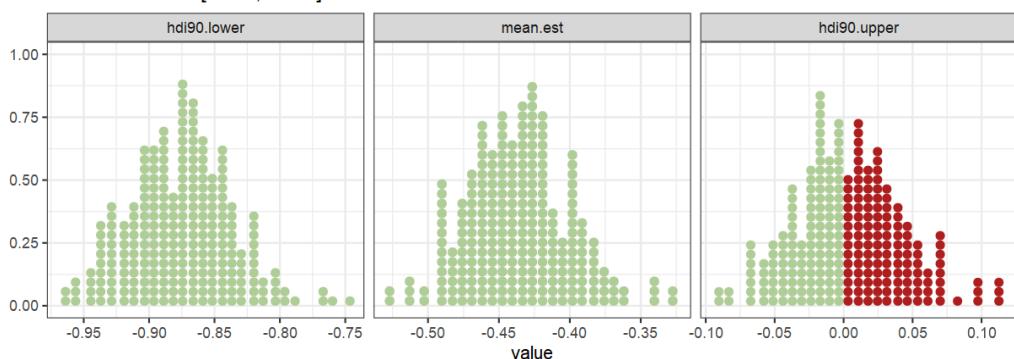

Microbivory flux - mean difference of soil treatments
main text: 0.59 [0.4, 0.78]

Detritivory flux - mean difference of 'soil but no plant history' to 'no soil history'
main text: -0.83 [-1.22, -0.45]

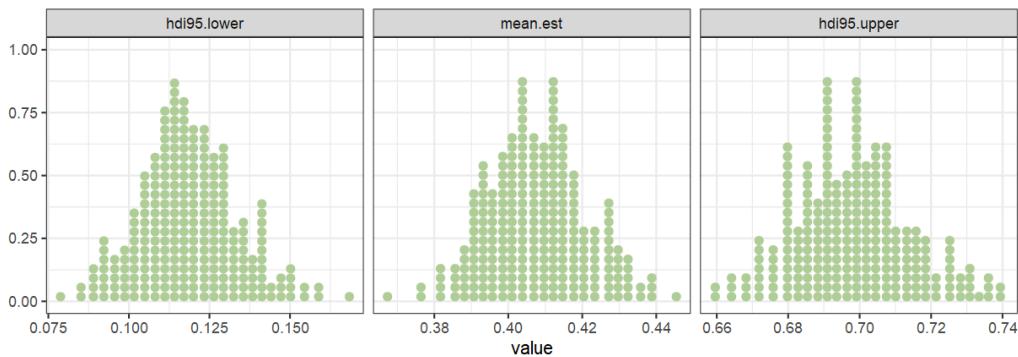

Detritivory flux - mean difference of plant treatments in communities with soil history
main text: -0.44 [-0.87, -0.01]

FigureS2 cont.

Fauna community biomass - mean difference of soil treatments
main text: 0.41 [0.125, 0.705]

CWM Body-mass - mean difference of soil treatments
main text: -0.64 [-0.94, -0.36]

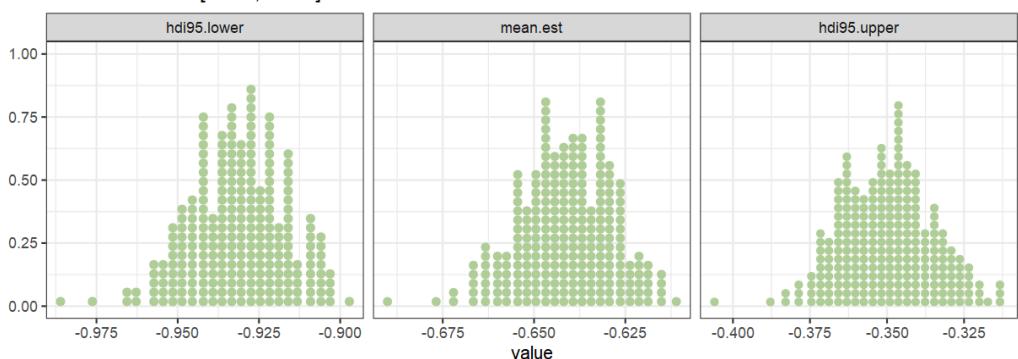

Figure S2 (cont.)

Table S3 Average abundance of broad groups across the experimental mesocosms. Taxa have been aggregated to broad groups. The detailed list of taxa abundance in each mesocosm is available in the supplementary data files.

Taxonomic group	Average abundance
Herbivorous nematodes	122321.68
Microbivorous nematodes	61888.23
Omnivorous nematodes	31522.56
Predatory nematodes	14108.97
Collembola	6156.25
Oribatid mites	4657.22
Prostigmatid mites	1354.07
Mesostigmatid mites	846.24
Astigmatid mites	23.73
Protura	167.71
Syphyla	78.13
Pauropoda	66.67
Diplura	6.37
Chilopoda	79.75
Hemiptera	73.61
Diplopoda	56.25
Staphylinidae	8.80
Other coleoptera	6.25
Diptera	4.40
Gastropoda	3.82
Spiders	1.74

Table S4 The invertebrate taxa that comprise the soil food webs of the JenaTron mesocosms. Agility, physical protection, metabolites and the vertical stratification of each taxon is from (2). The first three attributes are used as weights, so that when <1, they decrease the probability of consumption of that taxon as prey. Vertical stratification is used to construct a Bray-Curtis dissimilarity matrix, which again modifies consumption probability based on the overlap of predator and prey.
