Abstract

We construct an infinite dimensional Lie rackoid Y which hosts an integration of the standard Courant algebroid. As a set, $Y = \mathcal{C}^\infty([0, 1], T^*M)$ for a compact manifold M . The rackoid product is by automorphisms of the Dorfman bracket. The first part of the article is a study of the Lie rackoid Y and its tangent Leibniz algebroid a quotient of which is the standard Courant algebroid. In a second part, we study the equivalence relation related to the quotient on the rackoid level and restrict then to an integrable Dirac structure. We show how our integrating object contains the corresponding integrating Weinstein Lie groupoid in the case where the Dirac structure is given by a Poisson structure.

Introduction

Courant algebroids, introduced by Courant [4] in 1990, permit to treat Poisson structures and presymplectic structures on an equal footing. Courant algebroids are not Lie algebroids, but contain lots of Lie algebroids, namely the Lie algebroids associated to Dirac structures. Courant and Dirac geometry gained much interest during the last 20 years and have become central subjects in Poisson geometry.

Courant algebroids are not a classical differential geometric structure, as they are not related to Lie groups or Lie algebras, but rather to Leibniz algebras. A Courant algebroid carries a bracket which can be either expressed as an antisymmetric bracket which does not satisfy the Jacobi identity (Courant bracket [4]), or as a non-antisymmetric bracket satisfying the Leibniz identity (Dorfman bracket [7]). Therefore classical integration theory for Lie algebras or Lie algebroids does not apply, and the search for a global differential geometric object integrating a given Courant algebroid was wide open until lately.

Mehta-Tang [13], Li Bland-Severa [11] and Sheng-Zhu [18] attacked the problem of integrating Courant algebroids and found solutions in the realm of graded differential geometry. It is not easy to work with these solutions and in particular, the authors did not give hints about how to extract from their global objects the Lie groupoids integrating integrable Dirac structures in the Courant algebroid - concerning the latest progress in this direction, see [15]. We believe that the integrating object which we propose in the present article remedies this and reveals the Lie groupoids corresponding to integrable Dirac structures more easily, to the cost of working with an unusual, but natural differential geometric structure.

In the present article, we introduce an object integrating the standard Courant algebroid on $\mathbb{T}M = TM \oplus T^*M$ on a compact manifold M . As it comes from an integration of the underlying Leibniz algebroid $\mathbb{T}M$ and in some sense Leibniz algebras can be integrated into Lie racks in the same way as Lie algebras can be integrated into Lie groups, we dubbed it a *Lie rackoid*, see [10] where this notion appears for the first time.

In order to prepare the basic facts about Lie rackoids, compare our article [10]. We give there the basic definitions concerning Lie rackoids and show that the tangent object of a Lie rackoid is a Leibniz algebroid and every Lie groupoid has an underlying Lie rackoid. The intuition which goes with Lie rackoids is that in the same way as a rack retains from the structure of a group only the conjugation (forgetting the group product), a Lie rackoid can be viewed as a Lie groupoid where one retains only the conjugation. It is thus natural that the product structure in a Lie rackoid brings bisections of a (pre)category into play.

In a nutshell, a Lie rackoid is a smooth precategory $Y \underset{s}{\overset{t}{\rightrightarrows}} M$ with a rack product on its bisections and a compatible rack action of bisections on elements of Y . The bisections of a precategory over a compact manifold M form a Fréchet manifold (see [17], [10] Proposition 3.3) and the rack product on bisections is supposed to be smooth with respect to this manifold structure and the rack action is supposed to be by diffeomorphisms of Y . Our basic object in the present article is the Lie rackoid of (smooth) cotangent maps $Y = \{a : [0, 1] \rightarrow T^*M\}$. The precategory Y has as its source and target the projections to the starting- and end-point of the path a . The bisections of Y are of the form $\Sigma = (\phi, \eta)$ where $\phi_0 = \text{id}_M$ and ϕ_1 is some diffeomorphism of M , and η is a path of cotangent vectors. The matching between attachment points is such that $\phi_s^* \eta_s$ is a 1-form on M for each $s \in [0, 1]$. We denote

$$\beta_\Sigma = \int_0^1 \phi_s^* \eta_s ds$$

the 1-form on M naturally attached to the bisection Σ . The rack product on bisections reads then for $\mathcal{T} = (\psi, \zeta)$

$$\Sigma \triangleright \mathcal{T} = (\phi_1^{-1} \circ \psi_t \circ \phi_1, \phi_1^*(\zeta_t - i_{\psi_t}(\phi_1^{-1})^* d\beta_\Sigma)),$$

while the rack action of a bisection on an element $a = (\gamma, \theta)$ of Y is given by

$$\Sigma \triangleright a = (\phi_1^{-1}(\gamma), \phi_1^*(\theta - i_{\gamma_t}(\phi_1^{-1})^* d\beta_\Sigma)).$$

Note that the group of automorphisms of the Dorfman bracket of the standard Courant algebroid on $\mathbb{T}M$ is the semidirect product of diffeomorphisms and closed 2-forms [1], and such an automorphism $(\phi_1, d\beta_\Sigma)$ acts exactly in the way displayed above.

The Lie rackoid Y is an infinite-dimensional Lie rackoid (first main theorem: Theorem 2.12) whose infinitesimal Leibniz algebroid A admits a quotient isomorphic to the standard Courant algebroid (Proposition 3.7). In Section 5, we define an equivalence relation giving rise to a Fréchet foliation (Corollary 5.5) which corresponds to the passage to the quotient on the global level. In our second main theorem, we show that the Lie rack of bisections $\text{Bis}(Y)$ factors to a quotient rack $\text{Bis}(Y)/\sim$ which has a manifold structure and the correct tangent space in $(\text{id}, 0) \in \text{Bis}(Y)$, see Theorem 5.7.

We will call a subbundle $D \subset \mathbb{T}M$ a *Dirac structure* if it is maximally isotropic and its sections are closed under the Dorfman bracket. In this case, the Dorfman bracket reduces to a Lie bracket on the section of the subbundle D and D becomes a Lie algebroid. We call a Dirac structure D *integrable* if the underlying Lie algebroid is integrable, i.e. integrates into a Lie groupoid. The identification of the integrable Dirac structures (inside A and its quotient) and the corresponding Lie groupoids (inside Y and its quotient) takes the following form, see Section 5.2. Given a Dirac structure $D \subset \mathbb{T}M$, there are subobjects $A(D) \subset A$ and $Y_D \subset Y$ defined by

$$A(D)_m := \{(X_t, \alpha_t) \in A_m \mid (\dot{X}_t, \alpha_t) \in D_m \ \forall t \in [0, 1]\}$$

and

$$Y_D := \{(\gamma_t, \alpha_t) \in Y \mid (\dot{\gamma}, \alpha) \in D_{\gamma(t)} \ \forall t \in [0, 1]\}.$$

We strongly believe that the identification of integrable Dirac structures inside our Leibniz algebroid A and of their associated Lie groupoids inside our Lie rackoid work for a general integrable Dirac structure D , but for the moment, we can show these only for Dirac structures coming from integrable Poisson structures on M .

For this class of Dirac structures, we show that Y_D is a subrackoid (Proposition 5.12) and that with respect to the above equivalence relation, Y_D/\sim is a Lie rackoid isomorphic to the Lie rackoid underlying the symplectic Lie groupoid (smooth Weinstein groupoid) integrating the Dirac structure D (Corollary 5.15 and Proposition 5.19).

The link between D and Y is facilitated by the intrinsic symplectic geometry of Y , see Section 4. In terms of the symplectic 2-form ω on Y , inherited from T^*M , the 2-form $d\beta_\Sigma$ is just the pull-back of ω by the bisection Σ , viewed as a section of the source map.

Acknowledgements: This work has been done during the last five years and has been the subject of many visits of FW to Metz and Paris, as well as visits of CLG to Max Planck Institut in Bonn. We thank all the involved institutions for their kind hospitality and excellent working conditions. We

thank furthermore Christoph Wockel who has been part of this project for some time for his insights and contributions.

1 The path rackoid

We refer to [10], Section 3 for the basic definitions concerning Lie rackoids. The goal of the present section is to define the path Lie rackoid which is part of the Lie rackoid of cotangent paths integrating the standard Courant algebroid. The path rackoid serves here as an introduction to the rackoid of cotangent paths.

Let M be a finite dimensional compact manifold. Let X be the set of smooth paths $\gamma : [0, 1] \rightarrow M$. Then X is a smooth Fréchet manifold with respect to the \mathcal{C}^∞ -topology (with left resp. right derivatives of all orders in $0 \in [0, 1]$ resp. $1 \in [0, 1]$), see [14] Theorem 10.4, p. 91. It becomes a smooth precategory introducing source and target maps $s, t : X \rightarrow M$ which send a path γ to its starting point $\gamma(0)$ and its end point $\gamma(1)$ respectively. The unit map associates to $m \in M$ the constant path in m .

A Lie rackoid structure (see [10] for definitions) is a structure on the bisections of a smooth pre-category. Therefore we determine in the following lemma the set of bisections $\text{Bis}(X)$. Note that $\text{Bis}(X)$ carries a smooth Fréchet manifold structure obtained as in Proposition 3.3 of [10]. Indeed, by topologizing path spaces putting systematically the factor $[0, 1]$ to the left (using the bijection from the exponential law $\mathcal{C}^\infty(A \times B, C) = \mathcal{C}^\infty(A, \mathcal{C}^\infty(B, C))$), one deals only with finite-dimensional compact manifolds.

Lemma 1.1. The Fréchet manifold of smooth bisections $\text{Bis}(X)$ of the precategory $s, t : X \rightarrow M$ is

$$\text{Bis}(X) = \{ \gamma : [0, 1] \rightarrow \mathcal{C}^\infty(M, M) \mid \gamma_0 = \text{id}_M \text{ and } \gamma_1 \text{ diffeomorphism} \}.$$

Proof. A bisection of the precategory Y is by definition a map $\sigma : M \rightarrow Y$ such that $s \circ \sigma = \text{id}_M$ and $t \circ \sigma$ is a diffeomorphism of M . Let us view maps from M to $\mathcal{C}^\infty([0, 1], M) = X$ as maps from $[0, 1]$ to $\mathcal{C}^\infty(M, M)$, i.e. as paths in $\mathcal{C}^\infty(M, M)$ under this identification. The requirements on such a path γ in $\mathcal{C}^\infty(M, M)$ to be a bisection are clearly that $\gamma_0 = \text{id}_M$ and that γ_1 is a diffeomorphism of M . \square

A Lie rackoid is, roughly speaking (see Definition 3.5 in [10]) a smooth precategory X together with a smooth rack product on its manifold of bisections and a smooth rack action on X itself.

In the case at hand, we define on $\text{Bis}(X)$ a rack product for two bisections φ and ψ by

$$(\psi \triangleright \varphi)_{t,m} = \psi_1^{-1} \varphi_{t, \psi_1(m)},$$

for all $t \in [0, 1]$ and all $m \in M$, and a rack action for a bisection ψ and an element $\gamma \in X$ by

$$(\psi \triangleright \gamma)(t) = (t \mapsto \psi_1^{-1}(\gamma(t))).$$

Let us check the self-distributivity relation for three bisections φ , ψ and χ :

$$\begin{aligned} (\chi \triangleright (\psi \triangleright \varphi))_{t,m} &= \chi_1^{-1} \psi_1^{-1} \varphi_{t, \psi_1(\chi_1(m))} \\ &= \chi_1^{-1} \psi_1^{-1} \chi_1 \chi_1^{-1} \varphi_{t, \chi_1 \chi_1^{-1} \psi_1 \chi_1(m)} \\ &= ((\chi \triangleright \psi) \triangleright (\chi \triangleright \varphi))_{t,m}. \end{aligned}$$

This shows that X becomes a (unital, infinite dimensional) Lie rackoid.

Proposition 1.2. There is a surjective morphism of rackoids from X to the rackoid underlying the fundamental groupoid associating to a path its homotopy class.

2 The Lie rackoid of cotangent paths

In this section, we define the central object of this article, namely the Lie rackoid of cotangent paths. This Lie rackoid and a quotient of it are the object we propose for an integration of the standard Courant algebroid. The Lie rackoid which we have constructed in the previous section constitutes the first component of the Lie rackoid of cotangent paths.

2.1 Definition of the Lie rackoid of cotangent paths

Let M be a finite dimensional compact manifold and let $\pi : T^*M \rightarrow M$ denote its cotangent bundle. Consider the set of smooth *cotangent paths* in M , i.e.

$$Y = \{(\gamma, \eta) : [0, 1] \rightarrow T^*M \mid \eta \text{ smooth}\}.$$

Here the actual cotangent path is η and η contains the *base path* $\gamma = \pi \circ \eta$. For better readability of the upcoming formulae, the splitting into base path and (total) cotangent path maybe helpful.

The set Y is a smooth Fréchet manifold with respect to the C^∞ -topology and a smooth precategory over M with respect to the compositions $\pi \circ \text{ev}_0$ and $\pi \circ \text{ev}_1$ of the evaluation in 0 and 1 with the bundle projection π .

Again, in order to define a Lie rackoid structure, we determine the manifold of bisections $\text{Bis}(Y)$ of the pre-category Y .

Lemma 2.1. The bisections $\text{Bis}(Y)$ are the pairs $\Sigma = (\phi, \eta)$ where the first component ϕ is an element of the path Lie rackoid. The second component $s \mapsto \eta_s$ is a section of the bundle $\phi_t^* T^*M$ to which we can associate a path of 1-forms $s \mapsto \tilde{\eta}_s$ on M by setting

$$T_m M \ni X \mapsto \tilde{\eta}_s(X) := \eta_{s,m}(T_m \phi_s(X)).$$

Proof. The first part is very similar to the proof of Lemma 1.1, the second part is immediate from the definitions. \square

Remark 2.2. We denote the 1-form $\tilde{\eta}_s$ by $\phi_s^*\eta_s$. Observe that this is an abuse of notation. In fact, the *value* of η_s at $m \in M$, i.e. $\eta_{s,m}$, is already a cotangent vector at $\phi_s(m)$, but the tangent vector X at m has to be taken to $\phi_s(m)$ by $T_m\phi_s$. Thus η_s is somehow the *halfway* pullback $\phi_s^*\eta_s$. This is a natural operation on the bundle $\phi_t^*T^*M$.

In order to define the Lie rackoid, we now define a rack action for a bisection Σ acting on a cotangent path $a \in Y$. Composing a with the bundle projection $\pi : T^*M \rightarrow M$ gives an underlying path $\gamma := \pi \circ a$, $[0, 1] \ni s \mapsto \gamma_s$, on M with cotangent vectors θ_s attached to γ_s for all $s \in [0, 1]$. We let the bisection Σ act on the given cotangent path (γ, θ) according to the following formula:

$$\Sigma \triangleright a = (\phi_1^{-1}(\gamma), \phi_1^*(\theta - i_{\dot{\gamma}_t}(\phi_1^{-1})^*d(\int_0^1 \phi_s^*\eta_s ds))). \quad (1)$$

Remark 2.3. Let us comment on the algebraic form of the bracket operation. The bracket in Equation (1) is composed of the natural action by diffeomorphisms on the base path and on the cotangent path θ . Added to this is the *gauge transformation* using a certain exact 2-form $d\int_0^1 \phi_s^*\eta_s ds$. To understand this better, observe that there is a map $\varphi : Y \rightarrow \mathcal{C}^\infty([0, 1], \mathbb{T}M)$ which sends elements of $(\gamma, \theta) \in Y$ to $(\dot{\gamma}, \theta) \in \mathcal{C}^\infty([0, 1], \mathbb{T}M)$, where $\mathbb{T}M = TM \oplus T^*M$ is the extended tangent bundle of M . Recall the fact (see [1], Proposition 2.3) that the automorphism group of the standard Courant algebroid on the extended tangent bundle $\mathbb{T}M$ is the semidirect product $\Omega_{\text{cl}}^2(M) \rtimes \text{Diff}(M)$ of $\text{Diff}(M)$ and $\Omega_{\text{cl}}^2(M)$ where diffeomorphism and closed 2-form act exactly in this way. We therefore conclude that the action in Equation (1) is sent under φ to the natural action of an automorphism of the standard Courant algebroid.

Definition 2.4. The 1-form $\int_0^1 \phi_s^*\eta_s ds$ on M is canonically associated to the bisection $\Sigma = (\phi, \eta)$. We denote it by definition as

$$\beta_\Sigma := \int_0^1 \phi_s^*\eta_s ds.$$

Lemma 2.5. Formula (1) defines an element of Y , i.e. a cotangent path.

Remark 2.6. There is a similar rackoid product on tangent paths given by

$$\phi \triangleright a = (\phi_1(\gamma), (\phi_1^{-1})^*(\theta)).$$

This is in some sense the *opposite* of the above rack product without the *cocycle term*. It is easy to see that the associated Leibniz algebroid (see Theorem 5.3 in [10]) to this Lie rackoid is the vector bundle with typical fiber

$$A_m = \{a : [0, 1] \rightarrow T_m M \mid a(0) = 0\}$$

and whose ancre map is the evaluation in 1. The associated Leibniz bracket on the sections reads

$$[a(t), b(t)] = [a(1), b(t)].$$

This is closely related to the generalized Poisson bracket on the dual of a Leibniz algebra of Dhérin-Wagemann [6].

For the Lie rackoid structure on Y , we will also need a rack product on $\text{Bis}(Y)$. In fact, it can be derived from the above rack action in Equation (1) by acting with a bisection on the bisection *associated* to the corresponding element of Y . This means that Formula (1) induces a formula of the bisection acting on another bisection by viewing a bisection as a subset of Y and applying the first formula point-by-point to the elements of Y constituting it. This procedure permits in general to derive from some kind of action on a precategory the corresponding kind of product on the bisections.

Lemma 2.7. The formula for the action of a bisection on a bisection associated to Formula (1) is

$$\Sigma \triangleright \mathcal{T} = (\phi_1^{-1} \circ \psi_t \circ \phi_1, \phi_1^*(\zeta_t - i_{\psi_t}(\phi_1^{-1})^* d\beta_\Sigma)), \quad (2)$$

where $\Sigma = (\phi, \eta)$, $\mathcal{T} = (\psi, \zeta)$ and β_Σ the associated 1-form of Σ (cf Definition 2.4).

Proof. Let us discuss separately first and second component of the bisection.

Concerning the first component, we have to show that when we view ψ_t in $\phi_1^{-1} \circ \psi_t \circ \phi_1$ not as a family of maps in $\mathcal{C}^\infty(M, M)$, but rather as a subset of $\pi \circ Y = \mathcal{C}^\infty([0, 1], M)$ and we apply to each point individually the formula

$$(\phi \triangleright \gamma)(t) = (t \mapsto \phi_1^{-1}(\gamma(t))),$$

then we obtain $\phi_1^{-1} \circ \psi_t \circ \phi_1$. To do this, look at $\psi \in \mathcal{C}^\infty([0, 1], \mathcal{C}^\infty(M, M)) = \mathcal{C}^\infty(M, \mathcal{C}^\infty([0, 1], M))$ as a subset $\{\psi^m\}_{m \in M} \subset Y = \mathcal{C}^\infty([0, 1], M)$. An individual ψ^m may be viewed as a path γ in the above formula which we may therefore apply. Observe that in order to compare the result, we must take in

$$\phi \triangleright \{\psi^m\}_{m \in M} = \{\phi_1^{-1}(\psi^m(t))\}_{m \in M, t \in [0, 1]}$$

the path starting in $m \in M$, i.e. $\phi_1^{-1}(\psi^{\phi_1(m)})(t)$, and this is exactly the path in $\mathcal{C}^\infty(M, M)$ which is described by $\phi_1^{-1} \circ \psi_t \circ \phi_1$.

In the same way, we also treat the second component. It is clear that the cotangent vectors ζ_t , brought back to the path $\phi_1^{-1} \circ \psi_t \circ \phi_1$ via ϕ_1^* , correspond to the cotangent vectors $\phi_1^* \theta$ in Equation (1) along the path. Concerning the second factor of the second component, the terms are similar, with the exception of i_{ψ_t} which requires interpretation. Indeed, ψ_t is seen as associating to each $t \in [0, 1]$ a tangent vector to $\mathcal{C}^\infty(M, M)$ at $\psi(t)$, i.e. as a family of tangent vectors to the path ψ_t . The operation $\phi_1^*(i_{\psi_t}(\phi_1^{-1})^*(-))$ renders it then the insertion of a tangent vector to the path $\phi_1^{-1} \circ \psi_t \circ \phi_1$. \square

Let us compute the canonical 1-form associated to the bisection $\Sigma \triangleright \mathcal{T}$. Recall that we denote by $\beta_\Sigma = \int_0^1 \phi_s^* \eta_s ds$ the 1-form associated to $\Sigma = (\phi, \eta)$ and denote by $\beta_\mathcal{T} = \int_0^1 \psi_s^* \zeta_s ds$ the 1-form associated to $\mathcal{T} = (\psi, \zeta)$.

Lemma 2.8. The 1-form associated to $\Sigma \triangleright \mathcal{T}$ is

$$\beta_{\Sigma \triangleright \mathcal{T}} = \phi_1^* \beta_\mathcal{T} - \phi_1^* \int_0^1 \psi_s^* i_{\psi_s}(\phi_1^{-1})^* d\beta_\Sigma ds.$$

Proof. This is straight forward:

$$\int_0^1 (\phi_1^{-1} \circ \psi_s \circ \phi_1)^* \phi_1^* (\zeta_s - i_{\psi_s} (\phi_1^{-1})^* d\beta_\Sigma) ds = \phi_1^* \beta_\Sigma - \phi_1^* \int_0^1 \psi_s^* i_{\psi_s} (\phi_1^{-1})^* d\beta_\Sigma ds.$$

□

2.2 Selfdistributivity of the rackoid product

Now we show that the rackoid product proposed in Formula (1) satisfies the self-distributivity equation

$$\Sigma \triangleright (\mathcal{T} \triangleright a) = (\Sigma \triangleright \mathcal{T}) \triangleright (\Sigma \triangleright a).$$

This implies then that it defines a Lie rackoid structure on the set of cotangent paths. For this, we need the following lemma:

Lemma 2.9. Let ψ_t be a smooth path of maps in $\mathcal{C}^\infty(M, M)$ with ψ_0 and ψ_1 diffeomorphisms and $\mu \in \Omega^1(M)$. Then we have

$$d \int_0^1 \psi_s^* i_{\psi_s} d\mu ds = \psi_1^* d\mu - \psi_0^* d\mu.$$

Proof. We have

$$d \int_0^1 \psi_s^* i_{\psi_s} d\mu ds = \int_0^1 d(\psi_s^* i_{\psi_s} d\mu) ds.$$

Let us show that

$$d\psi_s^* i_{\psi_s} d\mu = \frac{d}{ds} \psi_s^* d\mu.$$

For this, we may suppose that $\mu = fdg$ and therefore that $d\mu = df \wedge dg$. With this expression, we obtain

$$\psi_s^* d\mu = d(f \circ \psi_s) \wedge d(g \circ \psi_s),$$

and then

$$\begin{aligned} \frac{d}{ds} \psi_s^* d\mu &= \frac{d}{ds} (d(f \circ \psi_s) \wedge d(g \circ \psi_s)) \\ &= d(T_{\psi_s} f(\dot{\psi}_s)) \wedge d(g \circ \psi_s) + d(f \circ \psi_s) \wedge d(T_{\psi_s} g(\dot{\psi}_s)) \\ &= d\psi_s^* \left((df(\dot{\psi}_s))dg + (dg(\dot{\psi}_s))df \right) \\ &= d\psi_s^* i_{\dot{\psi}_s} d\mu. \end{aligned}$$

This implies then

$$\begin{aligned} d \int_0^1 \psi_s^* i_{\dot{\psi}_s} d\mu ds &= \int_0^1 \frac{d}{ds} \psi_s^* d\mu ds. \\ &= \psi_1^* d\mu - \psi_0^* d\mu. \end{aligned}$$

□

This lemma permits us to find an easy expression for the de Rahm differential of the canonical 1-form $\beta_{\Sigma \triangleright \mathcal{T}}$ of $\Sigma \triangleright \mathcal{T}$ described in Lemma 2.8 in terms of the 1-forms β_Σ of Σ and $\beta_\mathcal{T}$ of \mathcal{T} :

Corollary 2.10. The 2-form $d\beta_{\Sigma \triangleright \mathcal{T}}$ corresponding to the rack product of Σ and \mathcal{T} has the following expression:

$$d\beta_{\Sigma \triangleright \mathcal{T}} = \phi_1^* d\beta_\mathcal{T} - \phi_1^* \psi_1^* (\phi_1^{-1})^* d\beta_\Sigma + d\beta_\Sigma.$$

Proof. By Lemmas 2.8 and 2.9, we have with $\mu = (\phi_1^{-1})^* \beta_\Sigma$ and $\psi_0 = \text{id}_M$

$$\begin{aligned} d\beta_{\Sigma \triangleright \mathcal{T}} &= \phi_1^* d\beta_\mathcal{T} - \phi_1^* d \int_0^1 \psi_s^* i_{\psi_s} (\phi_1^{-1})^* d\beta_\Sigma ds. \\ &= \phi_1^* d\beta_\mathcal{T} - \phi_1^* (\psi_1^* ((\phi_1^{-1})^* d\beta_\Sigma) - \psi_0^* ((\phi_1^{-1})^* d\beta_\Sigma)) \\ &= \phi_1^* d\beta_\mathcal{T} - \phi_1^* \psi_1^* (\phi_1^{-1})^* d\beta_\Sigma + d\beta_\Sigma. \end{aligned}$$

□

Remark 2.11. Observe that the expression for the 2-form $d\beta_{\Sigma \triangleright \mathcal{T}}$ in Corollary 2.10 is the transformation of a closed 2-form under conjugation in the semidirect product $\Omega_{\text{cl}}^2(M) \rtimes \text{Diff}(M)$, cf Remark 2.3.

The following theorem is the first main results of this article.

Theorem 2.12. *Formula (1) defines a rack action of $\text{Bis}(Y)$ on Y , i.e. for all bisections Σ and \mathcal{T} in $\text{Bis}(Y)$ and all $a \in Y$, we have*

$$\Sigma \triangleright (\mathcal{T} \triangleright a) = (\Sigma \triangleright \mathcal{T}) \triangleright (\Sigma \triangleright a).$$

Proof. Let $\Sigma = (\phi, \eta)$ and $\mathcal{T} = (\psi, \zeta)$ be bisections in $\text{Bis}(Y)$ and let $a = (\gamma, \alpha) \in Y$. Recall that $\phi = \phi_s$ and $\psi = \psi_s$ are paths of maps in $\mathcal{C}^\infty(M, M)$ with $\phi_0 = \psi_0 = \text{id}_M$ and ϕ_1, ψ_1 diffeomorphisms of M . Let us display mainly only the second components of the elements in $\text{Bis}(Y)$ or Y . The selfdistributivity in the first component has been checked in Section 1.

Recall also that the expression $\phi_s^* \eta_s$ is a 1-form and the notations

$$\beta_\Sigma = \int_0^1 \phi_s^* \eta_s ds, \text{ and } \beta_\mathcal{T} = \int_0^1 \psi_s^* \zeta_s ds.$$

With these notations, we have:

$$\mathcal{T} \triangleright a = (\psi_1^{-1}(\gamma), \psi_1^*(\alpha - i_{\gamma_t}(\psi_1^{-1})^* d\beta_\mathcal{T})),$$

$$\Sigma \triangleright a = (\phi_1^{-1}(\gamma), \phi_1^*(\alpha - i_{\gamma_t}(\phi_1^{-1})^* d\beta_\Sigma)),$$

and

$$\Sigma \triangleright \mathcal{T} = (\phi_1^{-1} \circ \psi_t \circ \phi_1, \phi_1^*(\zeta_t - i_{\psi_t}(\phi_1^{-1})^* d\beta_\Sigma)).$$

Putting these together, we obtain for the left hand side of the assertion of the theorem:

$$\Sigma \triangleright (\mathcal{T} \triangleright a) = (\phi_1^{-1} \psi_1^{-1}(\gamma_t), \phi_1^*(\psi_1^*(\alpha - i_{\dot{\gamma}_t}(\psi_1^{-1})^* d\beta_{\mathcal{T}}) - i_{\psi_1^{-1}(\dot{\gamma}_t)}(\phi_1^{-1})^* d\beta_{\Sigma})).$$

In the same way, we obtain (the same first component and for the second component of) (for) the right hand side of the assertion of the theorem, using Corollary 2.10 for an expression of $d\beta_{\Sigma \triangleright \mathcal{T}}$:

$$\begin{aligned} (\Sigma \triangleright \mathcal{T}) \triangleright (\Sigma \triangleright a) &= (\dots, (\phi_1^{-1} \psi_1 \phi_1)^*(\phi_1^*(\alpha - i_{\dot{\gamma}_t}(\phi_1^{-1})^* d\beta_{\Sigma}) + \\ &\quad - i_{(\phi_1^{-1})^*(\dot{\gamma}_t)}((\phi_1^{-1} \psi_1 \phi_1)^{-1})^* d\beta_{\Sigma \triangleright \mathcal{T}})) \\ &= (\dots, (\phi_1^{-1} \psi_1 \phi_1)^*(\phi_1^*(\alpha - i_{\dot{\gamma}_t}(\phi_1^{-1})^* d\beta_{\Sigma}) + \\ &\quad - i_{(\phi_1^{-1})^*(\dot{\gamma}_t)}((\phi_1^{-1} \psi_1 \phi_1)^{-1})^*(\phi_1^* d\beta_{\mathcal{T}} - \phi_1^* \psi_1^*(\phi_1^{-1})^* d\beta_{\Sigma} + d\beta_{\Sigma}))) \\ &= (\dots, \phi_1^* \psi_1^*(\alpha - i_{\dot{\gamma}_t}(\phi_1^{-1})^* d\beta_{\Sigma}) + \\ &\quad - \phi_1^* i_{(\psi_1^{-1})^*(\dot{\gamma}_t)}(d\beta_{\mathcal{T}} - \psi_1^*(\phi_1^{-1})^* d\beta_{\Sigma} + (\phi_1^{-1})^* d\beta_{\Sigma})) \end{aligned}$$

Here we have used that for a diffeomorphism $f : N \rightarrow M$, a vector field $X \in \mathcal{X}(N)$ and a 2-form $\omega \in \Omega^2(M)$:

$$i_X f^* \omega = f^* i_{f_* X} \omega,$$

and we used that

$$(\phi_1)_*(\phi_1^{-1} \dot{\gamma}_t) = \dot{\gamma}_t$$

as follows easily from the chain rule.

Observe that the terms involving α and $d\beta_{\mathcal{T}}$ coincide in the expressions of $\Sigma \triangleright (\mathcal{T} \triangleright a)$ and $(\Sigma \triangleright \mathcal{T}) \triangleright (\Sigma \triangleright a)$. The remaining terms in $(\Sigma \triangleright \mathcal{T}) \triangleright (\Sigma \triangleright a)$ are

$$\begin{aligned} -\phi_1^* \psi_1^* i_{\dot{\gamma}_t}(\phi_1^{-1})^* d\beta_{\Sigma} + \phi_1^* i_{(\psi_1^{-1})^*(\dot{\gamma}_t)} \psi_1^*(\phi_1^{-1})^* d\beta_{\Sigma} - \phi_1^* i_{(\psi_1^{-1})^*(\dot{\gamma}_t)}(\phi_1^{-1})^* d\beta_{\Sigma} = \\ -\phi_1^* i_{(\psi_1^{-1})^*(\dot{\gamma}_t)}(\phi_1^{-1})^* d\beta_{\Sigma}, \end{aligned}$$

and thus both expressions are equal. \square

Remark 2.13. In the light of Remarks 2.3 and 2.11, we can interpret Theorem 2.12 in a more conceptual way.

Indeed, recall the notion of an *augmented rack*, see e.g. [10]: Given a group G which acts on a set X such that there exists an equivariant map $p : X \rightarrow G$ (with respect to the conjugation action on G), X inherits the structure of a rack defined by $x \triangleright y := p(x) \cdot y$. In our context, the map

$$p : \text{Bis}(Y) \rightarrow \text{Aut}(\mathbb{T}M) = \Omega_{\text{cl}}^2(M) \rtimes \text{Diff}(M), \quad \Sigma = (\phi_s, \eta_s) \mapsto p(\Sigma) := (d\beta_{\Sigma}, \phi_1)$$

is in fact an augmented rack for the action of $(\theta, \psi) \in \text{Aut}(\mathbb{T}M)$ on $\Sigma \in \text{Bis}(Y)$ given by

$$(\theta, \psi) \cdot \Sigma := (\psi^{-1} \circ \phi_s \circ \psi, \psi^*(\eta_s - i_{\dot{\phi}_s}(\psi^{-1})^* \theta)).$$

The computations are very similar to the above proof.

Note that the above discussion implies in particular that p is a morphism of racks (with values in the conjugation rack underlying $\text{Aut}(\mathbb{T}M)$).

3 The Leibniz algebroid of cotangent paths

Here we will explore the infinitesimal/tangent Leibniz algebroid of Y , the *Leibniz algebroid of cotangent paths*. The general procedure associating to a Lie rackoid a tangent Leibniz algebroid can be found in Section 5.2 of [10].

3.1 Definition of the Leibniz algebroid

The Lie rackoid $Y = \{\gamma : [0, 1] \rightarrow T^*M\}$ has the underlying precategory the set of cotangent paths with the source s and target t maps to M induced by the starting- and endpoint projections. Its tangent Leibniz rackoid is by definition the kernel of Ts , i.e.

$$A := \Gamma_*([0, 1], TM \oplus T^*M).$$

A has as its underlying vector bundle the bundle of (pointed) paths over $I = [0, 1]$ in the extended tangent bundle $\mathbb{T}M = TM \oplus T^*M$. It is an infinite-dimensional vector bundle over M . The fiber at $m \in M$ is $\Gamma_*([0, 1], T_mM \oplus T_m^*M)$, the space of (pointed) paths in the vector space $T_mM \oplus T_m^*M$. The anchor in the Leibniz algebroid A is by definition the restriction of Tt , which is just the evaluation map $(X_t, \alpha_t) \mapsto X_1$ (up to a sign).

Let us compute the infinitesimal bracket with respect to the above Lie rackoid product given in Formula (1). It is a bracket on the space of sections of A , namely on

$$\Gamma(A) =: \mathfrak{Y} = \Gamma_*([0, 1], \text{Vect}(M) \oplus \Omega^1(M)).$$

Thus elements of \mathfrak{Y} are pairs (X_t, α_t) of a 1-parameter family of vector fields X_t with $X_0 = 0$ and a 1-parameter family of 1-forms α_t . The restriction on X_t comes from the fact that the family of diffeomorphisms ϕ_s satisfies $\phi_0 = \text{id}_M$.

Lemma 3.1. The infinitesimal bracket corresponding to Formula (1) reads

$$[(X_t, \alpha_t), (Y_t, \beta_t)] = ([X_1, Y_t], L_{X_1}\beta_t - i_{\dot{Y}_t}d \int_0^1 \alpha_s ds). \quad (3)$$

Proof. We apply the following procedure. Replace ϕ and ψ in Formula (2) by paths ϕ^s and ψ^s depending smoothly on a new parameter $s \in [-1, 1]$ such that at $s = 0$, both are the constant path in id_M , and $\frac{\partial}{\partial s}|_{s=0}\phi^s = X$ and $\frac{\partial}{\partial s}|_{s=0}\psi^s = Y$ are the corresponding paths of vector fields. The paths of 1-forms do not undergo much change. By definition of the Lie bracket of vector fields,

$$\frac{\partial}{\partial s}|_{s=0} \frac{\partial}{\partial u}|_{u=0} (\phi_1^u)^{-1} \circ \psi_t^s \circ \phi_1^u = [X_1, Y_t].$$

In the same vein, the first summand is by definition the Lie derivative with respect to X_1 . In the second summand of the second component, observe that by the product rule only the term with $i_{\dot{Y}_t}$ survives, and in this term, $\phi_1^0 = \text{id}_M$. \square

Lemma 3.2. The bracket in Equation (3) is a Leibniz bracket.

Proof. In view of Lemma 3.1, the claim does not need a proof. However, we will give a direct proof for the sake of transparency.

The (left) Leibniz identity is clear for the first component. In the second component, we have for $[(X_t, \alpha_t), [(Y_t, \beta_t), (Z_t, \gamma_t)]]$,

$$L_{X_1}(L_{Y_1}\gamma_t - i_{\dot{Z}_t} d \int_0^1 \beta_s ds) - i_{[Y_1, \dot{Z}_t]} d \int_0^1 \alpha_s ds,$$

for $[(X_t, \alpha_t), (Y_t, \beta_t)], (Z_t, \gamma_t)$,

$$L_{[X_1, Y_1]}\gamma_t - i_{\dot{Z}_t} d \int_0^1 (L_{X_1}\beta_s + i_{\dot{Y}_s} d \int_0^1 \alpha_u du) ds,$$

and for $[(Y_t, \beta_t), [(X_t, \alpha_t), (Z_t, \gamma_t)]]$,

$$L_{Y_1}(L_{X_1}\gamma_t - i_{\dot{Z}_t} d \int_0^1 \alpha_s ds) - i_{[X_1, \dot{Z}_t]} d \int_0^1 \beta_s ds.$$

We recollect the terms corresponding to α , β and γ which must cancel separately.

The fact that the Lie derivative is a representation takes care of the first terms in these three expressions:

$$L_{X_1}L_{Y_1}\gamma_t = L_{[X_1, Y_1]}\gamma_t + L_{Y_1}L_{X_1}\gamma_t.$$

The compatibility of the Lie derivative and the insertion operator (i.e. $[L_U, i_V] = i_{[U, V]}$) and the identity $dL_X = L_X d$ show that

$$L_{X_1}i_{\dot{Z}_t} d \int_0^1 \beta_s ds = i_{\dot{Z}_t} d \int_0^1 L_{X_1}\beta_s ds + i_{[X_1, \dot{Z}_t]} d \int_0^1 \beta_s ds.$$

Therefore, it remains to show

$$i_{[Y_1, \dot{Z}_t]} d \int_0^1 \alpha_s ds = i_{\dot{Z}_t} d \int_0^1 i_{\dot{Y}_s} d \left(\int_0^1 \alpha_u du \right) ds + L_{Y_1}i_{\dot{Z}_t} d \int_0^1 \alpha_s ds.$$

This last equality boils down (using again $[L_U, i_V] = i_{[U, V]}$ and $L_U d = di_U d$) to

$$\int_0^1 i_{\dot{Y}_s} d \left(\int_0^1 \alpha_u du \right) ds = i_{Y_1} d \int_0^1 \alpha_u du,$$

which follows from $\int_0^1 \dot{Y}_s ds = Y_1 - Y_0$ with the restriction $Y_0 = 0$. \square

3.2 The exponential map

The link of the infinitesimal picture with the global picture can be performed via the exponential map. The following lemma records formulae for the iterates of the Leibniz bracket:

Lemma 3.3. We have the following formulae for the iteration of the bracket introduced in Lemma (3.1):

(a)

$$\text{ad}_{(X,\alpha)}^{n+1}(Y, \beta) = \left(\text{ad}_X^{n+1}(Y), L_x^{n+1}\beta - \sum_{k=0}^n \binom{n+1}{k} i_{L_X^k Y} dL_X^{n-k}\alpha \right),$$

(b)

$$\begin{aligned} e^{\text{ad}_{(X,\alpha)}}(Y, \beta) &= \left(e^{\text{ad}_X}(Y), e^{L_X}\beta - \sum_{n=-1}^{\infty} \sum_{k=0}^n i_{\frac{L_X^k}{k!} Y} d \frac{L_X^{n-k}}{(n-k+1)!} \alpha \right), \\ &= \left(e^{\text{ad}_X}(Y), e^{L_X}\beta - i_{e^{L_X} Y} d \left(\frac{e^{L_X} - 1}{L_X} \right) \alpha \right). \end{aligned}$$

Remark 3.4. Recall the formula

$$(\Phi_t^X)^*(f) = \sum_{n \geq 0} \frac{t^n X^n(f)}{n!}$$

relating the flow Φ_t^X of a real analytic vector field X and the exponential of its action on a real analytic function f which is also valid for the action on other real analytic geometric objects on M . This formula follows from showing that the right hand side satisfies the same initial value problem

$$(\Phi_t^X)' = X \cdot \Phi_t^X, \quad \Phi_0^X = \text{id}_M$$

as the flow of X . For this, one inverts sum and derivative thanks to normal convergence, which is true on a compact manifold M .

This formula shows that the first component of $e^{\text{ad}_{(X,\alpha)}}(Y, \beta)$ is in fact $(\Phi_t^X)^* Y$, as expected.

3.3 The quotient standard Courant algebroid

In this section, we pass to a quotient of the Leibniz algebroid $A = \Gamma_*([0, 1], TM \oplus T^*M)$ with respect to a subalgebroid of ideals such that the quotient is isomorphic as Leibniz algebroids to the standard Courant algebroid.

Define the following subalgebroid in A :

$$I := \left\{ (X_t, \alpha_t) \mid X_1 = 0 \text{ and } \int_0^1 \alpha_s ds = 0 \right\}.$$

Observe that I is certainly a subbundle of the vector bundle A , as all requirements are $\mathcal{C}^\infty(M)$ -linear. That it is a subalgebroid will follow from the next lemma:

Lemma 3.5. The space of sections $\mathfrak{J} := \Gamma(I)$ is a (two-sided) Leibniz ideal contained in the left center of $\mathfrak{Q} = \Gamma(A)$.

Proof. It is obvious from the formula for the Leibniz bracket on the space of sections of A that have $[\mathfrak{J}, \mathfrak{Q}] = 0$, thus \mathfrak{J} is contained in the left center of the Leibniz algebra \mathfrak{Q} .

On the other hand, for $(X_t, \alpha_t) \in \mathfrak{Q}$ and $(Y_t, \beta_t) \in \mathfrak{J}$, we have

$$[(X_t, \alpha_t), (Y_t, \beta_t)] = ([X_1, Y_t], L_{X_1}\beta_t - i_{\dot{Y}_t} d \int_0^1 \alpha_s ds)$$

with $([X_1, Y_t])|_{t=1} = 0$ and

$$\int_0^1 (L_{X_1}\beta_t - i_{\dot{Y}_t} d \int_0^1 \alpha_s ds) dt = 0.$$

Indeed, the first factor in the integral is zero, because $\int_0^1 \beta_t dt = 0$, and the second factor in the integral is zero, because $\omega := \int_0^1 \alpha_s ds$ does not depend on t , and thus

$$\int_0^1 i_{\dot{Y}_t} d\omega dt = i_{Y_1} d\omega - i_{Y_0} d\omega = 0.$$

□

Remark 3.6. Observe that the squares of the Leibniz algebra \mathfrak{Q} are not included in \mathfrak{J} . Therefore the quotient is not necessarily a Lie algebra (as expected). Indeed, it is easily computed that the squares are of the form

$$([X_1, X_t], L_{X_1}\alpha_t - i_{\dot{X}_t} d \int_0^1 \alpha_s ds),$$

and, while $([X_1, X_t])|_{t=1} = 0$, the integral of the form-part gives

$$\begin{aligned} \int_0^1 (L_{X_1}\alpha_t - i_{\dot{X}_t} d \int_0^1 \alpha_s ds) dt &= L_{X_1}(\int_0^1 \alpha_s ds) - i_{X_1} d(\int_0^1 \alpha_s ds) \\ &= d i_{X_1}(\int_0^1 \alpha_s ds). \end{aligned}$$

Proposition 3.7. The map $\varphi := (\text{ev}_1, \int_0^1 (-) dt) : A \rightarrow \mathbb{T}M$ induces an isomorphism of Leibniz algebroids of A/I with the standard Courant algebroid $\mathbb{T}M$.

Proof. We claim that the map of vector bundles

$$\varphi = (\text{ev}_1, \int_0^1 (-) dt) : A \rightarrow \mathbb{T}M, \quad (X_t, \alpha_t) \mapsto (X_1, \int_0^1 \alpha_t dt)$$

is a morphism of Leibniz algebroids. Observe that the first component of φ is the anchor of A - this shows the compatibility of φ with the anchors.

The compatibility with the bracket is also immediate. Let (X_t, α_t) and (Y_t, β_t) be elements of \mathfrak{Y} and denote by $\omega := \int_0^1 \alpha_s ds$, $\zeta := \int_0^1 \beta_s ds$ the integration of the corresponding forms.

$$\begin{aligned} \varphi([(X_t, \alpha_t), (Y_t, \beta_t)]) &= ([X_1, Y_1], L_{X_1}\zeta - i_{X_1}d\omega) \\ &= [\varphi(X_t, \alpha_t), \varphi(Y_t, \beta_t)]. \end{aligned}$$

It is clear that the kernel of φ is the subalgebroid I from Lemma 3.5. \square

Remark 3.8. We have also a section for the map $\varphi := (\text{ev}_1, \int_0^1 (-) dt) : A \rightarrow \text{TM}$. It consists simply of the map $(X, \alpha) \mapsto (X_t : t \mapsto tX, \alpha)$ for $t \in [0, 1]$. It is easily computed that this section is compatible with the Leibniz bracket.

4 Symplectic geometry of the cotangent rackoid

4.1 Canonical 1-form and symplectic form

In this section, we interpret the form $d\beta_\Sigma = d \int_0^1 \phi_s^* \eta_s ds$ associated to a bisection $\Sigma = (\phi, \eta)$ in terms of a symplectic form. This is not mysterious as it is clear that the manifold of cotangent paths carries a symplectic structure inherited from the cotangent bundle.

Observe that there are the following three geometric objects defined on $Y = \mathcal{C}^\infty([0, 1], T^*M)$:

- (a) the function $c : (\gamma, \alpha) \mapsto \int_0^1 \alpha_{\gamma(t)}(\dot{\gamma}(t)) dt$,
- (b) the 1-form λ with $\lambda_{(\gamma, \alpha)}(\delta\gamma_t) = \int_0^1 \alpha_{\gamma(t)}(\delta\gamma_t) dt$ and
- (c) the exact 2-form $\omega = d\lambda$.

The 2-form ω is a symplectic form, thus the *symplectic manifold* Y is exact. Indeed, for any symplectic manifold S , the Fréchet manifold $\mathcal{C}^\infty([0, 1], S)$ is symplectic for the form obtained by integrating the pointwise form along $[0, 1]$, and in case S is exact, the resulting symplectic manifold $\mathcal{C}^\infty([0, 1], S)$ is exact as well, cf [3], [9].

The above three objects induce similar objects on the manifold of bisections $\text{Bis}(Y)$, and the 1-form λ on a bisection $\Sigma = (\phi, \eta)$ is the 1-form β_Σ which we introduced before. Denote by $s_\Sigma : \Sigma \rightarrow M$ the restriction of the source map $s : Y \rightarrow M$ to the bisection $\Sigma \subset Y$ and similarly for the target map $t : Y \rightarrow M$. View Σ as a section of the source map denoted $s_\Sigma^{-1} : M \rightarrow Y$.

Lemma 4.1. The pullback $(s_\Sigma^{-1})^*\lambda$ is the 1-form $\beta_\Sigma = \int_0^1 \phi_s^* \eta_s ds$. Thus $d\beta_\Sigma$ becomes the pullback of the symplectic form ω on Y and the pullback $(t_\Sigma^{-1})^*\lambda$ is $(\phi_1^{-1})^*\beta_\Sigma$.

Proof. Recall that we view bisections of Y , i. e. elements in

$$\mathcal{C}^\infty(M, \mathcal{C}^\infty([0, 1], T^*M)),$$

rather as elements of $\mathcal{C}^\infty([0, 1], \mathcal{C}^\infty(M, T^*M))$, i.e. as paths in $\mathcal{C}^\infty(M, T^*M)$. This is expressed in the notation (ϕ_t, η_t) . In order to perform the pullback, however, we have to view them as families of elements of Y , i.e. for a fixed $m \in M$, we obtain an element of Y which we denote accordingly $(\phi_t(m), \eta_t(m)) =: (\gamma_t, \alpha_t)$. We have to compute the expression of λ at such a point.

In fact, it is immediate that the expression $\lambda_{(\gamma, \alpha)} = \int_0^1 \alpha_{\gamma(t)}(\delta\gamma_t) dt$ computed at a point $(\phi_t(m), \eta_t(m)) =: (\gamma_t, \alpha_t)$ gives $\beta_\Sigma = \int_0^1 \phi_t^* \eta_t dt$. The only thing to note is that for all tangent vectors $X \in T_m M$, we have

$$(s_\Sigma^{-1})^*(\alpha_{\gamma(t)}(\delta\gamma_t))(X) = \eta_{t,m}(T_m\phi_t(X)).$$

The other claims of the lemma follow immediately from $(s_\Sigma^{-1})^*\lambda = \beta_\Sigma$. \square

Lemma 4.2. The three objects c , β_Σ and $d\beta_\Sigma$ on Y and $\text{Bis}(Y)$ respectively satisfy the following equivariance relations with respect to the rackoid product:

(a) the function c is invariant:

$$c_{(\gamma, \alpha)} = c_{\Sigma \triangleright (\gamma, \alpha)},$$

(b)

$$\beta_{\Sigma \triangleright \mathcal{T}} = \phi_1^* \beta_{\mathcal{T}} - \phi_1^* \int_0^1 \psi_s^* i_{\psi_s} (\phi_1^{-1})^* d\beta_\Sigma ds,$$

(c)

$$d\beta_{\Sigma \triangleright \mathcal{T}} = \phi_1^* d\beta_{\mathcal{T}} - \phi_1^* \psi_1^* (\phi_1^{-1})^* d\beta_\Sigma + d\beta_\Sigma. \quad (4)$$

Proof. (a) Straight forward computation.

(b) This has been shown in Lemma 2.8.

(c) This has been shown in Lemma 2.10. \square

Definition 4.3. A Lie rackoid with a closed 2-form on the underlying manifold (total space of the submersions) is called a *symplectic Lie rackoid* if the form satisfies the equivariance property displayed in Equation (4).

Definition 4.4. A bisection Σ of a Lie rackoid Y is called *isotropic* in case $d\beta_\Sigma = 0$.

The condition that a Lie groupoid is symplectic is much more restrictive than the condition that a Lie rackoid is symplectic. The former condition means that for the symplectic form ω on the symplectic groupoid $\Gamma \rightarrow M$, we have

$$0 = pr_1^* \omega - \text{comp}^* \omega + pr_2^* \omega,$$

where for $i = 1, 2$, $pr_i : \Gamma \times_M \Gamma \rightarrow \Gamma$ are the two projections and $\text{comp} : \Gamma \times_M \Gamma \rightarrow \Gamma$ is the composition. The fact that the relation contains three terms implies for example that the identity bisection $\epsilon : M \rightarrow \Gamma$ is isotropic. For a Lie rackoid, we have the following less restrictive property:

Lemma 4.5. In a symplectic Lie rackoid Y , the isotropic bisections form a subrack.

Proof. This follows from the property (c) above (resp. Lemma 2.10) together with $d\beta_\Sigma = 0$ and $d\beta_\mathcal{T} = 0$. \square

Proposition 4.6. The Lie rackoid associated to a symplectic Lie groupoid $\Gamma \rightarrow M$ is a symplectic Lie rackoid.

Proof. We refer to Proposition 5.1 in [10] for the Lie rackoid underlying a Lie groupoid.

The multiplicativity of the symplectic form in a symplectic Lie groupoid $\Gamma \rightarrow M$ can be expressed as

$$\omega_{\gamma_1 \gamma_2}(a \cdot b, c \cdot d) = \omega_{\gamma_1}(a, c) + \omega_{\gamma_2}(b, d),$$

where $\gamma_1, \gamma_2 \in \Gamma$ are composable, a, b, c, d are tangent vectors to Γ in γ_1 resp. γ_2 , and $(a, c) \mapsto a \cdot c$ is the product on the tangent groupoid associated to Γ .

Denoting by $*$ the group product on bisections of Γ , we obtain thus

$$\begin{aligned} \omega(\Sigma * \mathcal{T}(u), \Sigma * \mathcal{T}(v)) &= \omega(\Sigma(u) * \mathcal{T}((\phi_1)_*(u)), \Sigma(v) * \mathcal{T}((\phi_1)_*(v))) \\ &= \omega(\Sigma(u), \Sigma(v)) + \omega(\mathcal{T}((\phi_1)_*(u)), \mathcal{T}((\phi_1)_*(v))), \end{aligned}$$

for two tangent vectors u, v . Thanks to the fact that $d\beta_\Sigma$ is the pullback of the symplectic form on Y , this relation for all u, v translates into

$$d\beta_{\Sigma * \mathcal{T}} = d\beta_\Sigma + \phi_1^* d\beta_\mathcal{T}.$$

From this, we deduce first of all for the inverse bisection Σ^{-1} of Σ

$$0 = d\beta_{\Sigma * \Sigma^{-1}} = d\beta_\Sigma + \phi_1^* d\beta_{\Sigma^{-1}},$$

which implies then

$$d\beta_{\Sigma^{-1}} = -(\phi_1^{-1})^* d\beta_\Sigma.$$

With this, we compute

$$\begin{aligned} d\beta_{\Sigma * \mathcal{T} * \Sigma^{-1}} &= d\beta_\Sigma + \phi_1^* d\beta_{\mathcal{T} * \Sigma^{-1}} \\ &= d\beta_\Sigma + \phi_1^*(\psi_1^* d\beta_{\Sigma^{-1}} + d\beta_\mathcal{T}) \\ &= d\beta_\Sigma - \phi_1^* \psi_1^*(\phi_1^{-1})^* d\beta_\Sigma + \phi_1^* d\beta_\mathcal{T} \end{aligned}$$

This gives for the Lie groupoid, viewed as Lie rackoid:

$$d\beta_{\Sigma \triangleright \mathcal{T}} = d\beta_\Sigma + \phi_1^* d\beta_\mathcal{T} - \phi_1^* \psi_1^*(\phi_1^{-1})^* d\beta_\Sigma.$$

\square

4.2 Identifying Dirac structures inside A

Recall our Leibniz algebroid A , obtained by passing to the tangent Leibniz algebroid of the Lie rackoid of cotangent paths Y . Let $D \subset \mathbb{T}M$ denote a *Dirac structure*, i.e. a maximally isotropic subbundle of $\mathbb{T}M$ whose sections form a Leibniz subalgebra under the Dorfman bracket. This implies that the Dorfman bracket becomes a Lie bracket for the sections of the subbundle D and D is thus in a natural way a Lie algebroid. On top of this, we will always suppose that our Dirac structures are *integrable*, i.e. the Lie algebroid corresponding to D integrates into a Lie groupoid. This will play a role in Section 5 where we identify the Lie groupoids integrating Dirac structures inside Y .

To $D \subset \mathbb{T}M$, we associate a Leibniz subalgebroid $A(D)$ of A by

$$A(D)_m := \{(X_t, \alpha_t) \in A_m \mid (\dot{X}_t, \alpha_t) \in D_m \ \forall t \in [0, 1]\}$$

at each point $m \in M$. Observe that this defines a vector subbundle $A(D) \rightarrow M$ of $A \rightarrow M$.

Proposition 4.7. The restriction of the map $\varphi = (\text{ev}_1, \int_0^1 (-) dt) : A \rightarrow \mathbb{T}M$ to $A(D)$ has values in $D \subset \mathbb{T}M$.

Proof. We have

$$X_1 = \int_0^1 \dot{X}_t dt,$$

because $X_0 = 0$, and thus

$$\varphi(X_t, \alpha_t) = \int_0^1 (\dot{X}_t, \alpha_t) dt \in D_m,$$

because $(\dot{X}_t, \alpha_t) \in D_m$ for all $m \in M$. □

Proposition 4.8. The bracket on $\Gamma(A) = \mathfrak{Y}$ restricts to a bracket on $\Gamma(A(D))$:

$$[\Gamma(A(D)), \Gamma(A(D))] \subset \Gamma(A(D)).$$

Proof. For this, we first notice that the bracket of two elements in $\Gamma(A(D))$ may be written as an integral over $[0, 1]$:

$$\begin{aligned} [(X_s, \alpha_s), (Y_t, \beta_t)] &= ([X_1, Y_t], L_{X_1} \beta_t - i_{\dot{Y}_t} d \int_0^1 \alpha_s ds) \\ &= ([\int_0^1 \dot{X}_s ds, Y_t], \int_0^1 L_{\dot{X}_s} \beta_t ds - i_{\dot{Y}_t} d \int_0^1 \alpha_s ds) \\ &= \int_0^1 ([\dot{X}_s, Y_t], L_{\dot{X}_s} \beta_t - i_{\dot{Y}_t} d \alpha_s) ds. \end{aligned}$$

Next, the integrand $([\dot{X}_s, Y_t], L_{\dot{X}_s} \beta_t - i_{\dot{Y}_t} d \alpha_s)$ is in D_m at each point, because the Dirac structure is closed under the Courant (Dorfman) bracket. Thus

$$[(X_s, \alpha_s), (Y_t, \beta_t)] \in D_m$$

for all $t, s \in [0, 1]$. □

Corollary 4.9. The induced map $\varphi|_{A(D)} : A(D) \rightarrow D$ is a morphism of Leibniz algebroids. In particular, the kernel of (the induced map on the level of sections of) $\varphi|_{A(D)}$ contains (the intersection of $A(D)$ with) the ideal of squares.

Remark 4.10. Observe that we have used in this proof the fact that the Dirac structure is closed under the Courant (Dorfman) bracket.

We can also define the corresponding notion on the global level. Let

$$Y_D := \{(\gamma_t, \alpha_t) \in Y \mid (\dot{\gamma}, \alpha) \in D_{\gamma(t)} \ \forall t \in [0, 1]\}.$$

It is then clear that Y_D is a subprecategory of Y . The properties of Y_D will occupy a large space in the second half of Section 5.

5 Integration of the standard Courant algebroid

To integrate the standard Courant algebroid, we introduce an equivalence relation on the level of bisections $\text{Bis}(Y)$ and on the total space Y . The equivalence relation is rather difficult to handle, but well behaved at the point $(\text{id}, 0) \in \text{Bis}(Y)$. The corresponding infinitesimal Leibniz algebroid at $(\text{id}, 0)$ is isomorphic to the standard Courant algebroid. In the second half of this section, we study the behaviour of the equivalence relation on Y_D for Dirac structures D coming from integrable Poisson structures. We show that the corresponding quotient gives its integrating symplectic Lie groupoid.

5.1 The equivalence relation on $\text{Bis}(Y)$ and Y

The equivalence relation is the following. In order to formulate it, recall that we had shown for a bisection Σ that $\beta_\Sigma = (s_\Sigma^{-1})^*\lambda$ and $d\beta_\Sigma = (s_\Sigma^{-1})^*\omega$. In the following, we will deal with families of bisections $\{\Sigma_t\}_{t \in [0, 1]}$. For such a family, we introduce the notation $\check{\beta} = \check{\Sigma}^*\lambda = (s_\Sigma^{-1})^*\lambda \in \Omega^1([0, 1] \times M)$ and $\check{\omega} = \check{\Sigma}^*\omega = d\check{\beta} \in \Omega^2([0, 1] \times M)$, where $\check{\Sigma} : [0, 1] \times M \rightarrow Y$ is the map

$$(\epsilon, m) \mapsto (s \mapsto (\phi_s^{\Sigma_\epsilon}(m), \eta_s^{\Sigma_\epsilon}(m))).$$

On the other hand, we will view Σ_ϵ either as the member at ϵ of the family $\{\Sigma_t\}_{t \in [0, 1]}$ or as the map $\Sigma_\epsilon : [0, 1] \rightarrow \text{Bis}(Y)$. Denote by $u = \frac{\partial}{\partial t}$. Let us define $i_\epsilon : M \rightarrow M \times [0, 1]$ by $m \mapsto (m, \epsilon)$. We shall study the relation

$$\begin{aligned} \Sigma \sim \Sigma' \quad &:\Leftrightarrow \quad \phi_1 = \phi'_1 \quad \text{and} \\ &\exists \{\Sigma_t\}_{t \in [0, 1]} \quad \text{with} \quad \Sigma_0 = \Sigma, \quad \Sigma_1 = \Sigma' \quad \text{and} \quad i_\epsilon^* i_u \check{\omega} = 0. \end{aligned} \tag{5}$$

With loss of generality, we can assume that Σ_t is constant in some neighborhoods of 0 and 1 which allows to glue such families and thus implies that \sim is an equivalence relation.

Lemma 5.1. (a) The condition $i_\epsilon^* i_u \check{\omega} = 0$ is equivalent to $i_\epsilon^* d\check{\beta}(u) = \frac{\partial \beta_{\Sigma_\epsilon}}{\partial \epsilon}$.

(b) The condition $i_\epsilon^* i_u \check{\omega} = 0$ is equivalent to

$$\omega_Y \left(\frac{\partial \Sigma_t}{\partial t}(m), T\Sigma_t(\delta m) \right) = 0$$

for every tangent vector $\delta m \in T_m M$.

(c) The condition $i_\epsilon^* i_u \check{\omega} = 0$ is equivalent to the condition that $\frac{\partial \Sigma_t}{\partial t}$ is in the kernel of the map

$$T_\Sigma \mathcal{C}^\infty(M, Y) \supset T_\Sigma \text{Bis}(Y) \rightarrow \Omega^1(M), \quad \delta \Sigma \mapsto T\beta(\delta \Sigma) - i_\epsilon^* d\langle \lambda, \delta \Sigma \rangle.$$

Proof. (a) Recall the map $i_\epsilon : M \rightarrow M \times [0, 1]$ given by $m \mapsto (m, \epsilon)$. We have $d \circ i_\epsilon^* = i_\epsilon^* \circ d$ where one de Rham differential d is on M and the other on $M \times [0, 1]$. We claim that

$$\frac{\partial \beta_{\Sigma_\epsilon}}{\partial \epsilon} = i_\epsilon^* L_u \check{\beta}.$$

Indeed, if

$$\check{\beta} = \sum_i a_i(x, t) dx_i + b(x, t) dt,$$

we have on the one hand

$$i_\epsilon^* di_u \check{\beta} = \sum_i \frac{\partial b}{\partial x_i}(x, \epsilon) dx_i,$$

and on the other hand

$$i_\epsilon^* i_u d\check{\beta} = \sum_i \frac{\partial a_i}{\partial t}(x, \epsilon) dx_i - \sum_i \frac{\partial b}{\partial x_i}(x, \epsilon) dx_i.$$

But

$$\frac{\partial \beta_{\Sigma_\epsilon}}{\partial \epsilon} = \sum_i \frac{\partial a_i}{\partial t}(x, \epsilon) dx_i,$$

because $\beta_{\Sigma_\epsilon} = \sum_i a_i(x, \epsilon) dx_i$ is the restriction $\check{\beta}|_{M \times \{\epsilon\}}$ of $\check{\beta}$ to $M \times \{\epsilon\}$, whence the claim.

We obtain therefore

$$\begin{aligned} \frac{\partial \beta_{\Sigma_\epsilon}}{\partial \epsilon} &= i_\epsilon^* L_u \check{\beta} \\ &= i_\epsilon^* i_u d\check{\beta} + i_\epsilon^* di_u \check{\beta} \\ &= i_\epsilon^* i_u \check{\omega} + i_\epsilon^* di_u \check{\beta}. \end{aligned}$$

Thus the condition

$$i_\epsilon^* d\check{\beta}(u) = \frac{\partial \beta_{\Sigma_\epsilon}}{\partial \epsilon}$$

is equivalent to $i_\epsilon^* i_u \check{\omega} = 0$.

- (b),(c) Recall that the tangent space $T_\Sigma \mathcal{C}^\infty(M, Y)$ to $\mathcal{C}^\infty(M, Y)$ at a map $\Sigma : M \rightarrow Y$ consists of the maps $f : M \rightarrow TY$ such that $p \circ f = \Sigma$ where $p : TY \rightarrow Y$ is the canonical projection. Let us view β as a map

$$\beta : \text{Bis}(Y) \rightarrow \Omega^1(M), \quad \Sigma \mapsto \beta_\Sigma.$$

As $\text{Bis}(Y)$ inherits its manifold structure from $\mathcal{C}^\infty(M, Y)$, its tangent space at Σ is a subspace of $T_\Sigma \mathcal{C}^\infty(M, Y)$. The map $T\beta_{\Sigma_0}$, the value of the bundle map $T\beta$ at the bisection Σ_0 , sends a tangent vector $\delta\Sigma$ to $\text{Bis}(Y)$ at Σ_0 to a 1-form on M .

Therefore the condition

$$i_\epsilon^* d\check{\beta}(u) = \frac{\partial \beta_{\Sigma_\epsilon}}{\partial \epsilon}$$

in the congruence relation (5) is equivalent to the condition

$$i_\epsilon^* d\lambda \left(\frac{\partial \Sigma_\epsilon}{\partial \epsilon} \right) = T\beta_{\Sigma_\epsilon} \left(\frac{\partial \Sigma_\epsilon}{\partial \epsilon} \right). \quad (6)$$

This follows on the one hand from

$$T\beta_{\Sigma_\epsilon} \left(\frac{\partial \Sigma_\epsilon}{\partial \epsilon} \right) = \frac{\partial \beta_{\Sigma_\epsilon}}{\partial \epsilon},$$

and on the other hand from

$$\check{\beta}(u) = \langle \check{\Sigma}^* \lambda, u \rangle = \langle \lambda, T\check{\Sigma}(u) \rangle = \left\langle \lambda, \frac{\partial \Sigma_\epsilon}{\partial \epsilon} \right\rangle.$$

Note that Equation (6) implies

$$i_\epsilon^* d\lambda(\delta\Sigma) = T\beta_{\Sigma_\epsilon}(\delta\Sigma)$$

for each tangent vector $\delta\Sigma$ to $\text{Bis}(Y)$ as all of them may be described as being the derivative $\frac{\partial \Sigma_t}{\partial t}$ of a curve. In case a family of bisections $\{\Sigma_t\}_{t \in [0,1]}$ satisfies the equivalence relation, we have

$$\omega_Y \left(\frac{\partial \Sigma_t}{\partial t}(m), T\Sigma_t(\delta m) \right) = 0$$

for every tangent vector δm to M . Indeed, as $\check{\omega} = \check{\Sigma}^* \omega$, we have

$$\begin{aligned} i_\epsilon^* i_u \check{\omega} &= i_\epsilon^* \check{\omega} \left(\frac{\partial}{\partial t} \right) \\ &= i_\epsilon^* (\check{\Sigma}^* \omega) \left(\frac{\partial}{\partial t} \right) \\ &= i_\epsilon^* \omega \left(T\check{\Sigma}_* \left(\frac{\partial}{\partial t} \right), T\check{\Sigma}_*(-) \right) \\ &= i_\epsilon^* \omega \left(T\check{\Sigma}_* \left(\frac{\partial}{\partial t} \right), T\check{\Sigma}_*(-) \right) \\ &= \omega \left(\frac{\partial \Sigma_t}{\partial t}, T\Sigma_t(-) \right). \end{aligned}$$

□

Remark 5.2. Note that the property

$$i_\epsilon^* d\check{\beta}(u) = \frac{\partial \beta_{\Sigma_\epsilon}}{\partial \epsilon}$$

may be stated as the fact that the family of 1-forms β_{Σ_ϵ} on M is constant up to a well-determined exact form, namely $di_\epsilon^* \check{\beta}(u_\epsilon) = i_\epsilon^* d\check{\beta}(u_\epsilon)$. In particular, the exact 2-form $d\beta_{\Sigma_\epsilon}$ is constant. Therefore if $\Sigma \sim \Sigma'$, then $d\beta_\Sigma = d\beta_{\Sigma'}$.

Lemma 5.3. The equivalence relation is a *congruence relation*, i.e. if $\Sigma \sim \Sigma'$, then we have $\mathcal{T} \triangleright \Sigma \sim \mathcal{T} \triangleright \Sigma'$ and $\Sigma \triangleright \mathcal{T} \sim \Sigma' \triangleright \mathcal{T}$ for every bisection \mathcal{T} .

Proof. First note that $\Sigma \triangleright \mathcal{T} = \Sigma' \triangleright \mathcal{T}$, because $\Sigma \sim \Sigma'$ implies $\phi_1 = \phi'_1$ and $d\beta_\Sigma = d\beta_{\Sigma'}$, cf Remark 5.2. In particular, $\Sigma \triangleright \mathcal{T} \sim \Sigma' \triangleright \mathcal{T}$.

Now for the equality $\mathcal{T} \triangleright \Sigma \sim \mathcal{T} \triangleright \Sigma'$, consider three bisections Σ , Σ' and \mathcal{T} with $\Sigma \sim \Sigma'$. The goal is to show that

$$d\beta_{\mathcal{T} \triangleright \Sigma_\epsilon}(u_\epsilon)|_{\{\epsilon\} \times M} = \frac{\partial \beta_{\mathcal{T} \triangleright \Sigma_\epsilon}}{\partial \epsilon}, \quad (7)$$

because this implies then $\mathcal{T} \triangleright \Sigma \sim \mathcal{T} \triangleright \Sigma'$. Using Formula (2) for $\mathcal{T} \triangleright \Sigma_\epsilon$ (with $\phi_{\epsilon,s} = \phi_s^{\Sigma_\epsilon}$ (resp. ψ_s) the first component of Σ_ϵ (resp. \mathcal{T})), we have for the right hand side of Formula (7)

$$\begin{aligned} \frac{\partial \beta_{\mathcal{T} \triangleright \Sigma_\epsilon}}{\partial \epsilon} &= \frac{\partial}{\partial \epsilon} \psi_1^* \beta_{\Sigma_\epsilon} - \psi_1^* \int_0^1 \frac{\partial}{\partial \epsilon} \left(\phi_{\epsilon,s}^* i_{\frac{\partial \phi_{\epsilon,s}}{\partial s}} (\psi_1^{-1})^* d\beta_{\mathcal{T}} \right) ds \\ &= \psi_1^* d\check{\beta}(u_\epsilon) - \psi_1^* \int_0^1 \frac{\partial}{\partial \epsilon} \left(\phi_{\epsilon,s}^* i_{\frac{\partial \phi_{\epsilon,s}}{\partial s}} (\psi_1^{-1})^* d\beta_{\mathcal{T}} \right) ds. \end{aligned}$$

The left hand side of Formula (7) becomes

$$\begin{aligned} di_{u_\epsilon} \check{\beta}_{\mathcal{T} \triangleright \Sigma} &= d \int_0^1 \left\langle \eta_s^{\mathcal{T} \triangleright \Sigma_\epsilon} \left| \frac{\partial \phi_s^{\mathcal{T} \triangleright \Sigma_\epsilon}}{\partial \epsilon} \right. \right\rangle ds \\ &= d \int_0^1 \left\langle \psi_1^* \eta_s^{\Sigma_\epsilon} - \psi_1^* i_{\frac{\partial \phi_s^{\Sigma_\epsilon}}{\partial s}} (\psi_1^{-1})^* d\beta_{\mathcal{T}} \left| \frac{\partial (\psi_1^{-1} \phi_s^{\Sigma_\epsilon} \psi_1)}{\partial \epsilon} \right. \right\rangle ds \\ &= d \int_0^1 \left\langle \psi_1^* \eta_s^{\Sigma_\epsilon} - \psi_1^* i_{\frac{\partial \phi_s^{\Sigma_\epsilon}}{\partial s}} (\psi_1^{-1})^* d\beta_{\mathcal{T}} \left| (T\psi_1^{-1})_* \frac{\partial \phi_s^{\Sigma_\epsilon}}{\partial \epsilon} \right. \right\rangle ds \\ &= \psi_1^* d \int_0^1 \left\langle \eta_s^{\Sigma_\epsilon} \left| \frac{\partial \phi_s^{\Sigma_\epsilon}}{\partial \epsilon} \right. \right\rangle ds - \psi_1^* d \int_0^1 i_{\frac{\partial \phi_s^{\Sigma_\epsilon}}{\partial \epsilon}} i_{\frac{\partial \phi_s^{\Sigma_\epsilon}}{\partial s}} (\psi_1^{-1})^* d\beta_{\mathcal{T}} ds \\ &= \psi_1^* d\check{\beta}(u_\epsilon) - \psi_1^* d \int_0^1 i_{\frac{\partial \phi_s^{\Sigma_\epsilon}}{\partial \epsilon}} i_{\frac{\partial \phi_s^{\Sigma_\epsilon}}{\partial s}} (\psi_1^{-1})^* d\beta_{\mathcal{T}} ds \end{aligned}$$

In order to show Formula (7), it therefore remains to show

$$\int_0^1 \frac{\partial}{\partial \epsilon} \left(\phi_{\epsilon,s}^* i_{\frac{\partial \phi_{\epsilon,s}}{\partial s}} (\psi_1^{-1})^* d\beta_{\mathcal{T}} \right) ds = d \int_0^1 i_{\frac{\partial \phi_s^{\Sigma_\epsilon}}{\partial \epsilon}} i_{\frac{\partial \phi_s^{\Sigma_\epsilon}}{\partial s}} (\psi_1^{-1})^* d\beta_{\mathcal{T}} ds. \quad (8)$$

We will show this by restricting to a path $\gamma(t)$ in T^*M . Without loss of generality, we can assume the 2-form $(\psi_1^{-1})^* d\beta_{\mathcal{T}}$ to be $df \wedge dg$. Observing that the de Rahm differential d becomes on the path $\gamma(t)$ the derivative $\frac{\partial}{\partial t}|_{t=0}$, we obtain for the right hand side of Formula (8)

$$\int_0^1 \frac{\partial}{\partial t} \Big|_{t=0} \left(\frac{\partial}{\partial \epsilon} f(\phi_s^{\Sigma \epsilon}(\gamma(t))) \frac{\partial}{\partial s} g(\phi_s^{\Sigma \epsilon}(\gamma(t))) - \text{same with } (f \leftrightarrow g) \right) ds.$$

In the same vein, we obtain for the left hand side

$$\int_0^1 ds \frac{\partial}{\partial \epsilon} \left(\frac{\partial}{\partial s} g(\phi_s^{\Sigma \epsilon}(\gamma(t))) \frac{\partial}{\partial t} \Big|_{t=0} f(\phi_s^{\Sigma \epsilon}(\gamma(t))) \right) - \text{same with } (f \leftrightarrow g).$$

It is clear that integration par parts transforms one side of (the restriction to $\gamma(t)$ of) Formula (8) into the other. The boundary terms of the integration by parts involve derivatives with respect to ϵ for $s = 0$ or $s = 1$ of expressions in $\phi_s^{\Sigma \epsilon}$. But $\phi_0^{\Sigma \epsilon} = \text{id}_M$ and $\phi_1^{\Sigma \epsilon} = \phi_1$ is a fixed diffeomorphism, both being independent of ϵ . Therefore the derivatives, and as a consequence the boundary terms, are zero.

As the two sides of Formula (8) are thus equal when restricted to an arbitrary path $\gamma(t)$, they must be equal. \square

We now show the following differential geometric lemma concerning the manifold structure of the quotient with respect to the congruence relation:

Lemma 5.4. The map

$$T_{\Sigma} \mathcal{C}^{\infty}(M, Y) \supset T_{\Sigma} \text{Bis}(Y) \rightarrow \Omega^1(M), \quad \delta \Sigma \mapsto T\beta(\delta \Sigma) - i_{\epsilon}^* d\langle \lambda, \delta \Sigma \rangle$$

is split surjective.

Proof. A section to the map $T_{\Sigma} \text{Bis}(Y) \rightarrow \Omega^1(M)$ is constructed as follows. Let $\Sigma = (\phi_s, \eta_s) \in \text{Bis}(Y)$ be given. There exists a neighborhood V of $M \times \{0\}$ in $M \times [0, 1]$ such that for all $(m, t) \in V$, $m \mapsto \phi_t(m)$ is a diffeomorphism, because for $t = 0$, we have $\phi_0 = \text{id}_M$. Furthermore, there exists a real valued smooth function χ such that $\chi \equiv 0$ on the complement V^c of V in $M \times [0, 1]$ and $\int_0^1 \chi(m, t) dt = 1$ for each m which arises as projection of an element of V onto its first component.

Now construct the section

$$\omega : \Omega^1(M) \rightarrow T_{\Sigma} \text{Bis}(Y), \quad \alpha \mapsto \omega(\alpha)$$

as $\omega(\alpha) = \delta \eta_s$ where for a tangent vector $\delta m \in T_{\phi_s(m)} M$ we put

$$\delta \eta_s(\delta m) := \chi(m, t) \langle \alpha_m, T\phi_s^{-1}(\delta m) \rangle.$$

Up to a matching of attachment points using $T\phi_s^{-1}$, the section may be expressed as being the 1-form α , seen as a tangent vector to $\text{Bis}(Y) \subset \mathcal{C}^{\infty}(M, Y)$ which

is constant on $[0, 1]$ and has zero component in the T^*M -direction, multiplied with the cut-off function χ . Observe that this implies that $i_\epsilon^* d\langle \lambda, \delta\eta_s \rangle = 0$.

We therefore have

$$T\beta(\delta\eta_s)(\delta m) = \int_0^1 \phi_s^* \delta\eta_s(\delta m) ds = \int_0^1 \chi(m, s) \langle \alpha_m, \delta m \rangle ds = \langle \alpha, \delta m \rangle,$$

showing that ω is a section to the above map $T\beta - i_\epsilon^* d\langle \lambda, - \rangle$. \square

Corollary 5.5. The foliation given by the congruence relation is a regular Fréchet foliation.

Lemma 5.6. In the point $(\text{id}, 0) \in \text{Bis}(Y)$, the infinitesimal relation in $T_{(\text{id}, 0)}\text{Bis}(M)$ corresponding to the congruence relation (5) is

$$(X, \alpha) \in T_{(\text{id}, 0)}\mathcal{F} :\Leftrightarrow X_1 = 0 \text{ and } \int_0^1 \alpha_s ds = 0,$$

where \mathcal{F} is the leaf of the foliation corresponding to the congruence relation.

Proof. As a first condition, we get clearly $X_1 = 0$ from $\phi_1 = \text{id}_M$.

Using the expression of the map in Lemma 5.1 (c), the congruence relation reads in $\Sigma = (\text{id}, 0)$ as $T\beta_{(\text{id}, 0)} = 0$, because $\lambda_{(\text{id}, 0)} = 0$.

Hence the tangent map $T\beta_{(\text{id}, 0)}$ of $\beta : \mathcal{C}^\infty(M, Y) \rightarrow \Omega^1(M)$, $\Sigma \mapsto \beta_\Sigma$ has a simple description, namely $T\beta_{(\text{id}, 0)}(X, \alpha) = \int_0^1 \alpha_s ds$. Thus we obtain as a second condition $\int_0^1 \alpha_s ds = 0$. \square

In conclusion, we have shown the second main theorem of this article:

Theorem 5.7. *The set of equivalence classes $\overline{\text{Bis}(Y)} := \text{Bis}(Y) / \sim$ of bisections of Y with respect to the equivalence relation (5) becomes a rack with the rack product induced from the rack product of bisections.*

The set of equivalence classes is a quotient of a Fréchet manifold by a regular Fréchet foliation whose associated distribution of tangent spaces gives the correct infinitesimal relation in $(\text{id}, 0)$, i.e. the quotient Leibniz algebra is isomorphic to the Leibniz algebra of sections $\Gamma(\mathbb{T}M)$ of the standard Courant algebroid.

Remark 5.8. Unfortunately, the quotient $\overline{\text{Bis}(Y)}$ is not a Lie rack. We were not even able to show that it is a local Lie rack. The rack operation is clearly smooth, but the foliation may be ill-behaved off $(\text{id}, 0)$.

5.2 Integration of Dirac structures inside $\mathbb{T}M$

In this section, we will identify the Lie groupoids corresponding to integrable Dirac structures in Y . We believe once again that this works for a general integrable Dirac structure D , but for the moment, we can show it only for integrable Dirac structures coming from Poisson structures π on M .

Let D be an integrable Dirac structure. We will consider Y_D , given by

$$Y_D = \{(\gamma_t, \alpha_t) \in Y \mid (\dot{\gamma}, \alpha) \in D_{\gamma(t)} \ \forall t \in [0, 1]\}.$$

The goal is to pass from an equivalence relation on $\text{Bis}(Y_D)$ to an interesting equivalence relation on Y_D itself such that the quotient Y_D / \sim of Y_D identifies with the (smooth) Weinstein groupoid associated to the integrable Dirac structure D .

The main idea is to perform symplectic reduction: Given a symplectic category X with source and target maps to the manifold M and symplectic form $\omega \in \Omega^2(X)$, consider a coisotropic subcategory $Y \subset X$. The distribution of subspaces of the tangent spaces given by $\ker(\omega)$ defines an integrable regular distribution on Y thanks to the fact that Y is coisotropic. Thus the quotient Y / \sim carries an induced non-degenerate closed 2-form, but the quotient is not a manifold in general (but rather some orbifold). In our case, an identification with the Weinstein groupoid which has been proven to be a manifold for an integrable Lie algebroid by Crainic-Fernandes [5] will let us conclude that Y_D / \sim is a manifold in the integrable case.

In order to proceed (we will take $X := Y$, the manifold of cotangent paths, and $Y := Y_D$ the subset of cotangent paths (γ_t, η_t) with $(\dot{\gamma}_t, \eta_t) \in D_{\gamma(t)}$ for all $t \in [0, 1]$), we have to show that our Y_D associated to a Dirac structure D is coisotropic with respect to the symplectic structure ω on Y which is just the symplectic form on T^*M taken pointwise on the path.

Lemma 5.9. For any Dirac structure D , Y_D is a coisotropic subset of Y .

Proof. The symplectic form on T^*M is $\sum_{i=1}^n dq_i \wedge dp_i$, where the tangent space to T^*M has the usual fourfold coordinates $(q_i, p_i, \frac{\partial}{\partial q_i}, \frac{\partial}{\partial p_i})$ with $i = 1, \dots, n$ in case $\dim(M) = n$. The symplectic form is zero on a subset of Y if for all $t \in [0, 1]$, there is no (t -dependent) tangent vector with vector part having a non-zero coefficient in some $(\frac{\partial}{\partial q_i}, \frac{\partial}{\partial p_i})$ for some $i = 1, \dots, n$.

Recall that a Dirac structure is a Lagrangian subbundle of $\mathbb{T}M$ which is involutive, i.e. its sections are closed under the Dorfman bracket. In particular, local sections of D are $v + \alpha \in \mathbb{T}M$ with $\alpha(v) = 0$.

Let us consider the tangent directions to elements $(\gamma_t, \eta_t) \in Y_D$. For this, let us fix paths $(\gamma_t, \eta_t) \in Y_D$ with values in a fixed algebroid leaf S_0 of the Dirac structure. The tangent direction to the η_t -component is just the direction given by η_t itself as the section η_t is linear in the fiber direction. The constraint $(\dot{\gamma}_t, \eta_t) \in D_{\gamma(t)}$ means thus that the tangent directions in direction of the path $\gamma(t)$ at t and in direction of η_t pair to zero for all $t \in [0, 1]$. In particular, the coefficient in $(\frac{\partial}{\partial q_i}, \frac{\partial}{\partial p_i})$ is zero for all $i = 1, \dots, n$. As a consequence, the symplectic form inherited from T^*M must be zero on paths in Y_D with values in the fixed leaf S_0 . But being coisotropic means for Y_D exactly that the paths with values in a fixed leaf are Lagrangian, thus we have shown that Y_D is coisotropic. \square

In order to show that Y_D is a subrackoid, we need two propositions.

Let $G_D \rightrightarrows M$ be a source connected Lie groupoid integrating D and let ω_D be the corresponding 2-form on G_D . In other words, ω_D is the symplectic form of the symplectic realization $G_D \rightrightarrows M$ of the Poisson manifold (M, π) .

Given a bisection $\bar{\Sigma} = (\phi_s, \eta_s)$ of G_D , there is a map

$$\bar{\Sigma} : \mathbb{T}M \xrightarrow{((\phi_1)_*, \phi_1^*)} \mathbb{T}M \xrightarrow{\bar{\Sigma}^* \omega_D} \mathbb{T}M$$

defined as the composition of $((\phi_1)_*, \phi_1^*) : \mathbb{T}M \rightarrow \mathbb{T}M$ pushing forward (resp. pulling back) tangent (resp. cotangent) vectors to M via the diffeomorphism ϕ_1 and then $\bar{\Sigma}^* \omega_D : \mathbb{T}M \rightarrow \mathbb{T}M$ sending (X, α) to $(X, \alpha - i_X \bar{\Sigma}^* \omega_D)$. The composition of these maps covers the infinitesimal automorphisms of the Dorfman bracket described in Proposition 2.3 of [1].

Proposition 5.10. Let $G_D \rightrightarrows M$ be a source connected Lie groupoid integrating D with 2-form ω_D . Let ϕ_1 be a diffeomorphism of M and $\bar{\Sigma}$ be a bisection of G_D over ϕ_1 , i.e. $\bar{\Sigma} = (\phi_s, \eta_s)$ with ϕ_1 the given diffeomorphism of M . Then the map

$$\bar{\Sigma} : \mathbb{T}M \xrightarrow{((\phi_1)_*, \phi_1^*)} \mathbb{T}M \xrightarrow{\bar{\Sigma}^* \omega_D} \mathbb{T}M$$

sends D to D .

Proof. The map $\bar{\Sigma}$ covers an infinitesimal automorphism of the Dorfman bracket. As $\bar{\Sigma} \in \text{Bis}(Y_D)$, this infinitesimal automorphism is inner, i.e. given by the Dorfman bracket with an element of $D \subset \mathbb{T}M$. As D is closed under the Dorfman bracket, the infinitesimal automorphism sends D to D . Thus the global automorphism which covers it must also send D to D . This last step follows from the fact that the exponential images in a Lie groupoid cover the identity-component subgroupoid, see Proposition 3.6.3, p. 134, in [12]. \square

Disposing of a Lie groupoid $G_D \rightrightarrows M$ integrating D makes it possible to integrate paths in the Lie algebroid $D \subset T^*M$ into paths in the groupoid G_D , i.e. we obtain an integration map $I : Y_D \rightarrow G_D$, obtained by evaluating the path in G_D in $1 \in [0, 1]$. This map can also be understood as the quotient map with respect to the homotopy relation, see [5].

We state the next proposition for Dirac structures induced by the graph of a Poisson structure, because we could not locate in the literature the corresponding statement for general Dirac structures.

We are convinced, however, that this extension is true, except that G_D is not obtained by symplectic reduction. Instead, it is obtained by dividing Y_D by the kernel of ω with the condition that the end points of the paths in Y_D are fixed. In particular ω_D may be degenerate.

Proposition 5.11. Let ω be the symplectic form on Y and ω_D be the symplectic form on G_D . We have the following situation:

$$\begin{array}{ccc} Y_D & \xrightarrow{i_D} & (Y, \omega) \\ \downarrow I & & \\ (G_D, \omega_D) & & \end{array}$$

Then the pullback $I^*\omega_D$ of ω_D to Y_D is equal to the restriction $i_D^*\omega$ of ω to Y_D .

Proof. This follows from [3] using the fact that G_D is the symplectic reduction of the coisotropic submanifold $Y_D \subset Y$. \square

After these preparations, we can come to the announced result.

Proposition 5.12. Let D be an integrable Dirac structure induced by the graph of a Poisson structure π on M . Then Y_D is a subrackoid of Y , i.e. for all $y \in Y_D$ and all bisections $\mathcal{T} \in \text{Bis}(Y_D)$, we have $\mathcal{T} \triangleright y \in Y_D$, and for all bisections $\Sigma, \mathcal{T} \in \text{Bis}(Y_D)$, we have $\Sigma \triangleright \mathcal{T} \in \text{Bis}(Y_D)$.

Proof. Observe that the bisections of Y_D are simply

$$\text{Bis}(Y_D) = \{\Sigma = (\phi, \eta) \in \text{Bis}(Y) \mid \forall m \in M, (\dot{\phi}^m_t, \eta_{(m,t)}) \in D_{\phi^m(t)}\},$$

where we recall that for the path $\phi \in \mathcal{C}^\infty(M, M)$, the corresponding family of paths in M is ϕ^m (cf proof of Lemma 2.7).

Notice that the 2-form in Proposition 5.10 is ω_D , while in our rack product, it is the 2-form of Y , i.e. ω , which takes its place. Thanks to Proposition 5.11, both forms coincide on Y_D , and therefore $d\beta_\Sigma = \Sigma^*\omega_D$ which implies then $\Sigma \triangleright \mathcal{T} \in \text{Bis}(Y_D)$ for $\Sigma, \mathcal{T} \in \text{Bis}(Y_D)$. Thus Y_D is a subrackoid of Y . \square

Now we will induce an equivalence relation (in fact even a congruence relation) on the coisotropic subset $Y_D \subset Y$. The congruence relation on the bisections $\text{Bis}(Y_D)$ is the same as for $\text{Bis}(Y)$ (see Equation (5)) with the difference that the family $\{\Sigma_t\}_{t \in [0,1]}$ must have values in Y_D :

- Definition 5.13.** (a) For $\Sigma, \Sigma' \in \text{Bis}(Y_D)$, we define that $\Sigma \sim \Sigma'$ in case there exists $\{\Sigma_t\}_{t \in [0,1]}$ where $\Sigma_t \in Y_D$ for all $t \in [0, 1]$, $\Sigma_0 = \Sigma$, $\Sigma_1 = \Sigma'$ and $i_\epsilon^* i_u \tilde{\omega} = 0$.
- (b) Call a path γ in Y_D a *homotopy* from $\gamma(0)$ to $\gamma(1)$ in case all families of bisections $\{\Sigma_t\}_{t \in [0,1]}$ which include γ at m_0 satisfy $i_\epsilon^* i_u \tilde{\omega}|_{m_0} = 0$. For $y, y' \in Y_D$, define $y \sim y'$ if there exists a homotopy γ from y to y' .
- (c) For $y, y' \in Y_D$, define $y \approx y'$ if there exists y_t with $y_0 = y$ and $y_1 = y'$ and $\dot{y}_t \in \ker(\omega_D)$ for all $t \in [0, 1]$.

Here we mean by “the bisection Σ includes the path γ at m_0 ” that for Σ , viewed as a map in $\mathcal{C}^\infty(M, \mathcal{C}^\infty([0, 1], M))$, there exists m_0 such that $\Sigma_{m_0} = \gamma$. Observe that the difference between the equivalence relations \sim and \approx on Y_D is that while $i_\epsilon^* i_u \tilde{\omega} = 0$ is true at all $m \in M$ for \approx , this is true only in m_0 for \sim .

The equivalence relation \approx induces in turn an equivalence relation \approx on bisections, namely $\Sigma_0 \approx \Sigma_1$ if there exists Σ_t from Σ_0 to Σ_1 such that $\frac{\partial \Sigma_t}{\partial t} \in \ker(\omega_D)$ for all $t \in [0, 1]$. Observe that $\Sigma_0 \approx \Sigma_1$ for two bisections $\Sigma_0, \Sigma_1 \in \text{Bis}(Y_D)$ implies $\Sigma_0 \sim \Sigma_1$ and $\Sigma_0 \triangleright - = \Sigma_1 \triangleright -$.

Lemma 5.14. The relation (b) on Y_D is a congruence relation, i.e. for all $y, y' \in Y_D$ with $y \sim y'$ and all $\mathcal{T} \in \text{Bis}(Y_D)$, we have $\mathcal{T} \triangleright y \sim \mathcal{T} \triangleright y'$.

Proof. Include the homotopy γ between y and y' into a family of bisections $\{\Sigma_t\}_{t \in [0,1]}$. Call the limiting bisections at 0 and 1 of $\{\Sigma_t\}_{t \in [0,1]}$ Σ and Σ' respectively. The bisections Σ and Σ' are *equivalent in* $m_0 \in M$. We have to show that $\mathcal{T} \triangleright \Sigma$ and $\mathcal{T} \triangleright \Sigma'$ are still *equivalent in some* $m_1 \in M$. Denote $\mathcal{T} = (\psi_t, \zeta_t)$, $\Sigma = (\phi, \eta)$ and $\Sigma' = (\phi', \eta')$. Our claim follows from the formula (see Corollary 2.10)

$$d\beta_{\mathcal{T} \triangleright \Sigma_t} = \psi_1^* d\beta_{\Sigma_t} - \psi_1^* \phi_{1,t}^* (\psi_1^{-1})^* d\beta_{\mathcal{T}} + d\beta_{\mathcal{T}}.$$

Indeed, when computing the condition $i_\epsilon^* i_u \tilde{\omega} = 0$ with this formula, i_u kills all terms which do not contain dt , thus we are left with the term in dt coming from $\psi_1^* d\beta_{\Sigma_t}$. One concludes by commuting ψ_1^* with i_ϵ^* and i_u . \square

Corollary 5.15. The quotient Y_D / \sim is a rackoid.

Proof. By Proposition 5.12, Y_D is a subrackoid of Y , and by Lemma 5.14, the equivalence relation is a congruence relation and respects thus the classes. \square

On the other hand, the symplectic reduction gives the Weinstein groupoid:

Theorem 5.16 (Cattaneo-Felder, Strobl). *Let π be an integrable Poisson bivector on the manifold M . Then the set of cotangent paths Y_π is a coisotropic subset of Y and the corresponding symplectic reduction gives the symplectic Weinstein groupoid integrating π .*

Proof. Cotangent paths Y_π for a bivector π form a coisotropic subset if and only if π is a Poisson bivector. This statement appears in different forms in the literature, cf Equation (10) in [16], Equation (7) in [8], Theorem 1.1 in [2] and Theorem 3.1 in [3].

The fact that the symplectic reduction in the Poisson case gives the Weinstein groupoid is shown in [3]. \square

Remark 5.17. We believe that this is valid for a general integrable Dirac structure. A hint in this direction is Theorem 2 (p. 22) in [9].

Thus in our framework, Y_D / \sim is the Weinstein groupoid. In order to link this approach to Crainic-Fernandes framework, we prove the following:

Proposition 5.18. The equivalence relation \sim on Y_D is the one given by the coisotropic foliation, i.e. relations (b) et (c) of Definition 5.13 coincide.

Proof. This assertion follows from the comparison of the two relations discussed above: On the one hand, the tangency to the leaves means for families of bisections $\{\Sigma_t\}_{t \in [0,1]}$ in Y_D

$$\omega_{Y_D} \left(\frac{\partial \Sigma_t}{\partial t}(m), \delta \Sigma \right) = 0$$

for every tangent vector $\delta\Sigma$ to Y_D . We claim that this property is equivalent to the property (see Lemma 5.1) which satisfies the family of bisections $\{\Sigma_t\}_{t \in [0,1]}$ in Y_D in our congruence relation, namely

$$\omega_{Y_D}\left(\frac{\partial \Sigma_t}{\partial t}(m), T\Sigma_t(\delta m)\right) = 0$$

for every tangent vector δm to M .

In order to show this, we have to construct for a given tangent vector $\delta\Sigma$ to Y_D a family $\{\Sigma_t\}_{t \in [0,1]}$ in Y_D and a tangent vector δm to M such that $T\Sigma_t(\delta m) = \delta\Sigma$. This follows from a contractibility property of Y_D . As elements of Y_D are sections of a vector bundle, one can contract the fiber component to zero and then the resulting path to the trivial path. This means that Y_D permits the extension of sections and bisections, and we can thus find a bisection passing through a given point or even passing through a given tangent vector. \square

Proposition 5.19. The rackoid structure on Y_D/\sim inherited from that of Y_D and the rackoid structure underlying the groupoid structure on the Weinstein groupoid $G := Y_D/\sim$ coincide.

Proof. The proof goes as follows. Let us describe the action of a bisection σ of a source simply connected Lie groupoid G on itself. Choose some $g \in G$ and let a be an A -path which represents g , with A the Lie algebroid of G . Then $\text{Ad}_\sigma(a)$ is again an A -path and it represents $\text{Ad}_\sigma(g)$. (Recall from [5], Section 1, that the set of homotopy classes of G -paths is homeomorphic to the set of homotopy classes of A -paths in the sense of [5]). Here Ad_σ stands for the adjoint action of the bisection σ on the Lie algebroid A .

For the Lie groupoid G_D integrating a Dirac structure D arising from a Poisson structure, the adjoint action of bisections goes as follows. To a bisection Σ of G_D , one associates a diffeomorphism ϕ_1 of the base and a closed 2-form: the pull-back $\Sigma^*\omega_{G_D}$ of the symplectic 2-form ω_{G_D} on G_D by the source map. The adjoint action of Σ on the Lie algebroid D is then the transformation described in Proposition 5.10.

Let us compare this action with the rackoid product \triangleright . For any bisection $\Sigma = (\phi_t, \eta_t)$ of Y , and for any $a = (\gamma, \theta) \in Y$, the rackoid product $\Sigma \triangleright a$ is obtained by associating to a the path (γ', θ) in $\mathbb{T}M$ and then acting on $\mathbb{T}M$ with the help of the transformation $\bar{\Sigma}$ defined as in Proposition 5.10. By this procedure, we obtain a path in $\mathbb{T}M$ lying over the path $\phi_1 \circ \gamma$. Its component in T^*M is an element of Y which is equal to $\Sigma \triangleright a$. Again, the rackoid product $\Sigma \triangleright -$ depends only on the pair $(\phi_1, d\beta_\Sigma)$, with ϕ_1, β_Σ as in Definition 2.4. In particular, for a bisection Σ of Y_D , the rackoid product $\Sigma \triangleright -$ depends only on the image of Σ in the set of bisections of G_D and, in view of Proposition 5.11, the closed 2-form $d\beta_\Sigma$ coincides with the closed 2-form $\Sigma^*\omega_{G_D}$ described above.

In conclusion, the rack product $\Sigma \triangleright a$, with Σ a bisection of Y_D and $a \in Y_D$ is equal to $\text{Ad}_\sigma(a)$, with σ the image of Σ in the set of bisection of Y_D . In view of the first paragraph, this completes the proof of the proposition. \square
