Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

Cryogenic Infrared Spectroscopy Reveals Structural Modularity in the Vibrational Fingerprints of Heparan Sulfate Diastereomers

ABSTRACT: Heparan sulfate and heparin are highly acidic polysaccharides with a linear sequence, consisting of alternating glucosamine and hexuronic acid building blocks. The identity of hexuronic acid units shows a variability along their sequence, as D-glucuronic acid and its C5 epimer, L-iduronic acid can both occur. The resulting backbone diversity represents a major challenge for an unambiguous structural assignment by mass spectrometry-based techniques. Here, we employ cryogenic infrared spectroscopy on mass-selected ions to overcome this challenge and distinguish isomeric heparan sulfate tetrasaccharides that differ only in the configuration of their hexuronic acid building blocks. High-resolution infrared spectra of a systematic set of synthetic heparan sulfate stereoisomers were recorded in the fingerprint region from 1000 to 1800 cm^{-1} . The experiments reveal a characteristic combination of spectral features for each of the four diastereomers studied, and imply structural modularity in the vibrational fingerprints. Strong spectrum-structure correlations were found and rationalized by state-of-the-art quantum chemical calculations. The findings demonstrate the potential of cryogenic infrared spectroscopy to extend the mass spectrometry-based toolkit for the sequencing of heparan sulfate and structurally related biomolecules.

Heparan sulfate and heparin are structurally closely related, sulfated representatives of glycosaminoglycans (GAGs), a class of acidic polysaccharides with a linear sequence of repeating disaccharide units^{1,2}. Being present in the extracellular matrix and at the surface of cells, they regulate various biological processes, ranging from hemostasis to inflammation and tumor metastasis³⁻⁵. The backbone of heparan sulfate and heparin consists of alternating α -D-glucosamine (GlcN, often acetylated as GlcNAc) and hexuronic acid building blocks. The identity of the hexuronic acid units varies in heparan sulfate and heparin chains: β -D-glucuronic acid (GlcA) and its C5 epimer, α -L-iduronic acid (IdoA) are both present. This backbone diversity is unique among GAGs and represents a major challenge for structural characterization.

Recent developments in electron-based ion dissociation methods enabled tandem mass spectrometry to overcome many difficulties in GAG analysis stemming from the presence of multiple sulfate groups⁶⁻⁹, and from the

potential variability of hexuronic acid stereochemistry¹⁰⁻¹². Despite these improvements, an unambiguous distinction between GlcA and IdoA in isomeric heparan sulfate sequences is still extremely challenging, and in certain cases may prove to be impossible by mass spectrometry alone¹³.

A promising strategy to unravel hexuronic acid stereochemistry is to employ ion mobility-mass spectrometry (IM-MS). IM-MS has been successfully applied for the analysis of intact GAG ions¹⁴⁻¹⁶, as well as of their fragments to facilitate the sequencing of larger structures in a bottom-up approach¹⁷. Besides improving the speed and confidence of analyte identification, IM-MS often enables the separation and differentiation of heparan sulfate ions that differ only in the stereochemistry of hexuronic acid building blocks. In certain cases, however, the mobilities of such diastereomers are too similar, impeding an unambiguous structural assignment by IM-MS.

Previous studies revealed that mass-selected GAG ions exhibit characteristic spectral features in the mid-

infrared^{18, 19} and OH-stretching region²⁰⁻²². Cryogenic temperatures in either messenger-tagging infrared (IR) spectroscopy²⁰ or helium nanodroplet IR spectroscopy¹⁸ are crucial in the identification of GAG ions larger than monosaccharides. Both cryogenic IR spectroscopy approaches yield spectra that are reproducible and comparable across laboratories and instruments²³. Building on these findings, we here employ cryogenic IR spectroscopy in helium nanodroplets to study the influence of hexuronic acid stereochemistry on the vibrational fingerprints of heparan sulfate oligosaccharide ions from 1000 to 1800 cm^{-1} .

Figure 1. Schematic depiction of the helium nanodroplet instrument for cryogenic IR spectroscopy. Ions generated by nanoelectrospray ionization (nESI) are m/z -selected in a quadrupole and accumulated in a cryogenic ion trap at 90 K. Here, the ions are picked up by traversing superfluid helium nanodroplets and cooled to their equilibrium temperature of 0.4 K. Helium droplet-embedded ions are irradiated by IR photons coming from the Fritz Haber Institute free-electron laser (FHI FEL). Upon resonant absorption of multiple infrared (IR) photons, ions are released from the nanodroplets and detected after time-of-flight analysis. Plotting the ion release yield as a function of photon energy results in high-resolution vibrational spectra of cold, mass-selected ions.

The utilized experimental setup is shown in Fig. 1 and has been described in detail previously^{24, 25}. In the present study, negative ions are generated by nanoelectrospray ionization (nESI), transferred to vacuum and isolated using a quadrupole mass filter. The m/z -selected anions are directed into a cryogenic hexapole ion trap (90 K) where they undergo buffer-gas cooling. Subsequently, a stream of superfluid helium nanodroplets traverse the trap to pick-up the anions, which rapidly cool to 0.4 K, the equilibrium temperature of the droplets. The He-embedded anions overcome the trapping potential and reach the interaction region, where they are irradiated with intense, tunable radiation from the Fritz Haber Institute free-electron laser (FHI FEL). Upon sequential resonant absorption of multiple photons, the ions are released from the droplets and detected in a time-of-flight mass analyzer. IR action spectra are generated by plotting the ion signal as a function of the incident photon energy.

For the experiments, a set of well-defined, aminoalkyl-linked synthetic heparan sulfate tetrasaccharides were chosen. The four tetrasaccharides represent a complete set of all possible permutations with repetitions of GlcA and

IdoA; the rest of the molecule is identical²⁶. The chemical structures are shown in Fig. 2 and in Fig. S1 (Supporting Information, SI) in their representation using the symbol nomenclature for glycans (SNFG). In the four tetrasaccharides, the configurations at two stereogenic C5 atoms are varied, which makes them diastereomers and in pairs epimers with only one alteration. These moderately sulfated tetrasaccharides were investigated as doubly deprotonated ions [molecule-2H]²⁻ with m/z 510, which makes them relatively stable in the gas-phase environment of a mass spectrometer¹⁸. The tetrasaccharides carry two 6O-sulfate functional groups (6S) at which the charges are localized¹⁹. Thus, charge migration and population of multiple deprotomers can be limited which decreases the spectral complexity^{18, 27}.

Cryogenic IR spectra in the fingerprint mid-IR range from 1000 to 1800 cm^{-1} were recorded and are shown in Fig. 2. All spectra consist of well-resolved lines, and the four diastereomers can be unambiguously distinguished from each other based on their IR signatures. Assignments of spectral lines within wavenumber ranges are based on theoretical calculations of disaccharides (Fig. S2, SI) and previously published calculations of sulfated monosaccharides¹⁹. For all four anions, the spectral features observed from 1000 to 1150 cm^{-1} can be assigned to combined C–O and C–C stretching vibrations of the glycan core. Additionally, the symmetric SO_3^- stretching modes of the sulfate functional groups are typically found around or below 1050 cm^{-1} and usually overlap. Spectral lines corresponding to the combined, antisymmetric SO_3^- stretching modes are observed between 1150 and 1350 cm^{-1} . Smaller features from 1200 to 1500 cm^{-1} correspond to multiple C–H and O–H bending modes. For the GlcNAc moieties, the amide I and II vibrations, the stretching vibration of the C=O and the combined bending modes of the N–H, respectively, are expected to be active between 1500 and 1700 cm^{-1} . Above 1700 cm^{-1} , spectral lines correspond to the C=O stretching vibration in the neutral carboxyl functional groups of GlcA and IdoA.

The region between 1000 and 1150 cm^{-1} in the spectra in Fig. 2 is congested for all four species. At higher wavenumbers, however, characteristic bands can be observed, allowing for specific assignments. In the spectra in Fig. 2a and 2c, a band at around 1175 cm^{-1} is observed. In the spectra in Fig. 2b and 2d, this band seems to be replaced by a band at ca. 1220 cm^{-1} . It is thus reasonable to assign the band at 1175 cm^{-1} to stem from the sulfate group in GlcA-GlcNAc6S and the band at ca. 1220 cm^{-1} from the sulfate group in IdoA-GlcNAc6S, both at the non-reducing end. Moving to higher wavenumbers, in all four spectra, a band is observed at 1295 cm^{-1} . To the higher wavenumber side in the spectra in Fig. 2c and 2d a band at 1330 cm^{-1} is observed, which appears to be connected to the presence of the sulfate group in IdoA-GlcNAc6S-L at the reducing end of the glycan. At higher wavenumbers around 1600 cm^{-1} , an intense band is observed in the spectra in Fig. 2c and 2d, which again coincides with the disaccharide IdoA-GlcNAc6S-L at the reducing end. The absorption bands in the region of the antisymmetric SO_3^- stretching modes are always present in two IR spectra—in an IR spectrum of a homogeneous diastereomer (either two GlcA or two IdoA) and in an IR

spectrum of a heterogeneous diastereomer (one GlcA and one IdoA)—with exception of the vibration at 1295 cm^{-1} .

The difference in the absorption pattern in the region of the antisymmetric SO_3^- stretching region likely reflects a hexuronic acid-dependent change in the chemical environment of the sulfate groups. With the variation in the

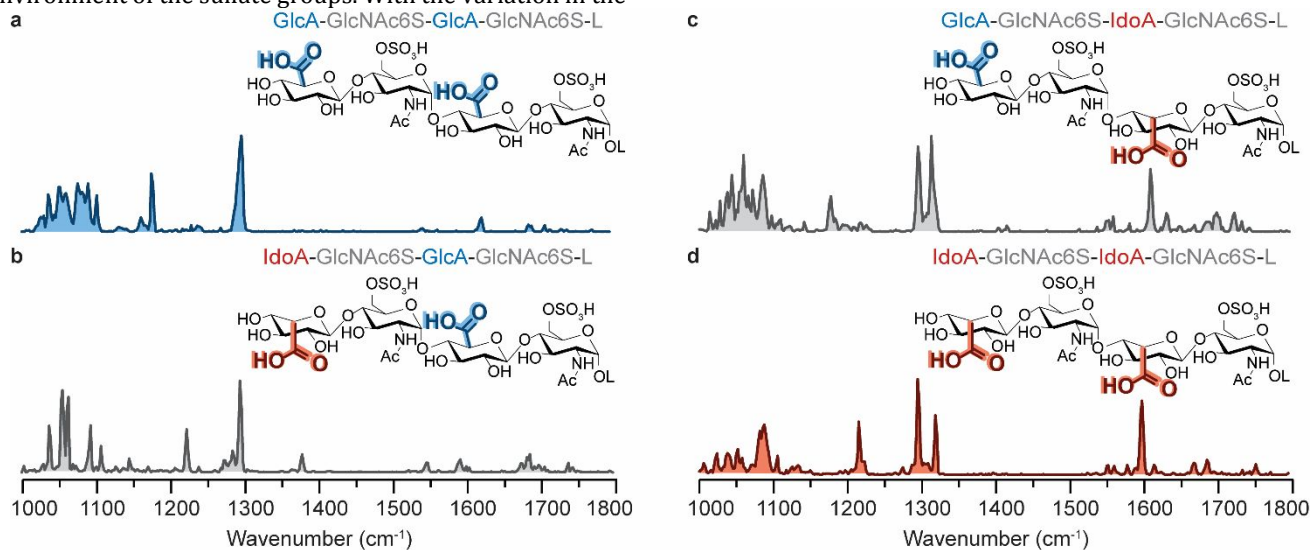

Figure 2. Cryogenic IR spectroscopy in helium nanodroplets from 1000 to 1800 cm^{-1} of heparan sulfate tetrasaccharides, **(a)** GlcA-GlcNAc6S-GlcA-GlcNAc6S-L, **(b)** IdoA-GlcNAc6S-GlcA-GlcNAc6S-L, **(c)** GlcA-GlcNAc6S-IdoA-GlcNAc6S-L, **(d)** IdoA-GlcNAc6S-IdoA-GlcNAc6S-L, investigated as [molecule-2H] $^{2-}$ anions with m/z 510. Abbreviated are β -D-glucuronic acid GlcA, α -L-iduronic acid IdoA, 6-O-sulfo-*N*-acetyl- α -D-glucosamine GlcNAc6S and aminoalkyl-linker L ($(\text{CH}_2)_5\text{NH}_2$) from synthesis.

To test whether the absorptions derive from chemically discrete modules of disaccharides in the tetrasaccharide, the linear combinations of the IR spectra of the homogeneous diastereomers and of the IR spectra of the heterogeneous diastereomers were constructed and are shown in Fig. 3a. Assuming discrete increments of disaccharides with discrete IR signatures, both linear combinations represent a 1:1:1:1 combination of the IR signatures of all possible disaccharide modules—GlcA-GlcNAc6S, IdoA-GlcNAc6S, GlcA-GlcNAc6S-L, IdoA-GlcNAc6S-L—at the non-reducing end or at the reducing end, adjacent to the aminoalkyl-linker L. In the region of the antisymmetric SO_3^- stretching modes and also around 1600 cm^{-1} , the two linear combinations reveal very similar absorption patterns, which becomes especially apparent in the overlay of the linear combinations in Fig. 3b. The IR signatures between 1000 and 1150 cm^{-1} and above 1600 cm^{-1} are more congested and, even though qualitatively matching, did not line up perfectly.

To investigate the structural motifs that lead to the differences in the IR signatures, the conformational space of the four disaccharides was explored using the evolutionary algorithm FAFOOM²⁸ with local density functional theory optimization in FHI-aims²⁹. Details on the theoretical methods are included in the SI. The sampled structures were screened for differences in the interaction between the carboxyl, amide, sulfate and potentially present aminoalkyl-linker with relevant distances less than 2 Å. For each building block, low-energy structures with these distinct interaction motifs were reoptimized, and vibrational frequencies were computed in Gaussian 16³⁰ at the PBE0-D3/6-31G(d)^{31, 32} level of theory for all atoms

except sulfur, for which the basis set 6-311+G(2df,2pd) was employed. Low-energy structures below an arbitrary threshold of 15 kJ mol^{-1} relative to the lowest-energy structure of each building block are listed with their type of interaction and their relative free energy in Table S1 (SI). The lowest-energy structure of each building block was reoptimized and the frequencies computed at PBE0-D3/ma-def2-TZVP^{33, 34} level of theory for all atoms.

The lowest-energy structures for the four disaccharides reveal four different structural motifs, which are depicted in Fig. 4a for the non-reducing end disaccharides GlcA-GlcNAc6S and IdoA-GlcNAc6S and in Fig. 4b for the disaccharides with aminoalkyl-linker GlcA-GlcNAc6S-L and IdoA-GlcNAc6S-L. The native disaccharide GlcA-GlcNAc6S predominantly forms a Type A pattern in hydrogen bonding in which the amide carbonyl oxygen acts as hydrogen bond acceptor for the neutral carboxyl OH.

Figure 3. (a) Linear combinations of the cryogenic IR spectra in helium nanodroplets from 1000 to 1800 cm^{-1} of the homogeneous diastereomers (upper panel) GlcA-GlcNAc6S-GlcA-GlcNAc6S-L and IdoA-GlcNAc6S-IdoA-GlcNAc6S-L and of the heterogeneous diastereomers (lower panel) IdoA-GlcNAc6S-GlcA-GlcNAc6S-L and GlcA-GlcNAc6S-IdoA-GlcNAc6S-L. (b) Overlay of the linear combinations. Abbreviated are β -D-glucuronic acid GlcA, α -L-iduronic acid IdoA, 6-O-sulfo-N-acetyl- α -D-glucosamine GlcNAc6S and aminoalkyl-linker L ((CH₂)₅NH₂).

The epimer IdoA-GlcNAc6S shows preference for a Type B hydrogen bonding pattern in which the charged sulfate group forms an ionic hydrogen bond with the neutral carboxyl. The structural motif in the disaccharides with aminoalkyl-linker is dominated by an interaction between three of the functional groups in question: the amide carbonyl from GlcNAc, the neutral carboxyl group from the hexuronic acid and the amino group from the linker.

Figure 4. Structural motifs in the lowest-energy structures for (a) GlcA-GlcNAc6S (left), IdoA-GlcNAc6S (right) and (b) GlcA-GlcNAc6S-L (left), IdoA-GlcNAc6S-L (right). Abbreviated are β -D-glucuronic acid GlcA, α -L-iduronic acid IdoA, 6-O-sulfo-N-acetyl- α -D-glucosamine GlcNAc6S and aminoalkyl-linker L ((CH₂)₅NH₂).

In conclusion, we show here that cryogenic IR spectroscopy is capable of unambiguously distinguishing isomeric heparan sulfate oligosaccharides that differ only in the configuration of hexuronic acid building blocks. In a wider context, the findings show that IR spectroscopy of mass-selected ions displays great potential for the analysis of heparan sulfate and heparin. Reference spectra from further small building blocks such as those reported here facilitates their identification. Cryogenic IR spectroscopy may be combined with off-line chromatographic or

electrophoretic separations, ion mobility spectrometry, or tandem MS techniques to significantly improve the fragment-based sequencing¹⁷ of longer GAG chains in the future. Furthermore, our study reveals a strong structure correlation for this set of ions, which results from key intramolecular interactions that are unique for the individual stereoisomers and can be directly linked to specific structural elements. It is not clear whether these unique structural motifs are preserved in larger GAG ions, which is an interesting question for further investigations. The differences in the detailed molecular structure of the ions will help to unravel differences in the currently poorly understood fragmentation behavior of GAGs in MS experiments.
