ABSTRACT: We show that the Newman-Janis shift property of the exact Kerr solution can be interpreted in terms of a worldsheet effective action. This holds both in gravity, and for the single-copy $\sqrt{\text{Kerr}}$ solution in electrodynamics. At the level of equations of motion, we show that the Newman-Janis shift holds also for the leading interactions of the Kerr black hole. These leading interactions are conveniently described using chiral classical equations of motion with the help of the spinor-helicity method familiar from scattering amplitudes.

1 Introduction

The Newman-Janis (NJ) shift [1] is a remarkable exact property of the Kerr solution [2] describing a stationary spinning black hole in general relativity. It relates the Kerr solution to the simpler non-spinning Schwarzschild solution. One way to understand this property is to consider the Weyl curvature spinor Ψ . With appropriate coordinates, the NJ shift is

$$\Psi^{\text{Kerr}}(x) = \Psi^{\text{Schwarzschild}}(x + ia), \quad (1.1)$$

where a is the spin of the Kerr metric. In other words, the Kerr solution looks like a complex translation of the Schwarzschild solution [3].

Precisely the same phenomenon occurs for the electromagnetic $\sqrt{\text{Kerr}}$ solution [1], which double-copies to the Kerr metric [4]. In this case, it is the Maxwell spinor ϕ that undergoes a shift:

$$\phi^{\sqrt{\text{Kerr}}}(x) = \phi^{\text{Coulomb}}(x + ia). \quad (1.2)$$

Therefore, $\sqrt{\text{Kerr}}$ is a kind of complex translation of the Coulomb solution.

A partial understanding of this NJ phenomenon is available in the context of scattering amplitudes. Although amplitudes are rooted in quantum field theory, in recent years there has been an explosion of interest in applications of amplitudes to classical physics [5–22]. This is motivated by the applicability of the results for elastic [23–44] and inelastic [45–57] gravitational scattering of two massive particles to gravitational-wave physics [58–72], as well as by the search for the underlying

principles behind the double-copy relationship between gauge theory and gravity [4, 73–90]. Recently, Arkani-Hamed, Huang and Huang [91] pointed out a special class of three-point amplitudes for a massive particle of spin s emitting a gauge boson or graviton. In a classical context, amplitudes for minimally coupled massive particles of large (classical) spin $s \gg 1$ are simple exponential factors times the amplitudes for scalar particles [15, 24, 30]. In particular, the $\sqrt{\text{Kerr}}$ three-point amplitude describing classical electromagnetic interactions of a minimally coupled, massive, charged particle with a classical spin length a is

$$\mathcal{A}_{3,+}^{\sqrt{\text{Kerr}}} = e^{-k \cdot a} \mathcal{A}_{3,+}^{\text{Coulomb}}. \quad (1.3)$$

Here $\mathcal{A}_{3,+}^{\text{Coulomb}} = -2Q(p \cdot \varepsilon_k^+)$ is the usual QED amplitude for a scalar of charge Q and momentum p absorbing a photon with positive-helicity polarisation vector ε_k^+ . Similarly, the gravitational three-point amplitude for a massive particle is

$$\mathcal{M}_{3,+}^{\text{Kerr}} = e^{-k \cdot a} \mathcal{M}_{3,+}^{\text{Schwarzschild}}, \quad (1.4)$$

in terms of the “Schwarzschild” amplitude for a scalar particle interacting with a positive-helicity graviton of momentum k . A straightforward way to establish the connection of these amplitudes to spinning black holes [24, 25, 30] is to compute the impulse on a scalar probe at leading order in the Kerr background [15]. The calculation can be performed using classical equations of motion on the one hand, and using scattering amplitudes and the KMOC formalism [13, 16, 18] on the other. A direct comparison of the two approaches makes it evident [15, 30] that the NJ shift of the background is captured by the exponential factors $e^{\pm k \cdot a}$.

This connection between the NJ shift and scattering amplitudes suggests that the NJ shift should extend beyond the exact Kerr solution to the *interactions* of spinning black holes. Indeed, it is straightforward to scatter two Kerr particles (by which we mean massive particles with classical spin lengths a_1 and a_2) off one another using amplitudes. The purpose of this paper is to investigate the classical interpretation of this fact. To do so, we turn to the classical effective theory describing the worldline interactions of a Kerr particle [92–96]. We will see that the NJ property endows this worldline action with a remarkable two-dimensional worldsheet structure. The Newman-Janis story emerges via Stokes’ theorem on this worldsheet with boundary and indeed persists for at least the leading interactions. We will see that novel equations of motion, making use of the spinor-helicity formalism in a purely classical context, allow us to make the shift manifest in the leading interactions.

Our effective action is constructed only from the information in the three-point amplitudes. At higher orders, information from four-point and higher amplitudes (or similar sources) is necessary to fully specify the effective action. Therefore our action is in principle supplemented by an infinite tower of higher-order operators. We may hope, however, that the worldsheet structure may itself constrain the allowed higher-dimension operators.

As applications of our methods, we use a generalisation of the Newman-Janis shift [97] to introduce magnetic charges (in electrodynamics) and NUT parameters (in gravity) for the particles described by our equations of motion. As an example, we compute the leading impulse on a probe particle with mass, spin and NUT charge moving in a Kerr-Taub-NUT background. The charged generalisation of the NJ complex map can similarly be connected to the behaviour of three-point amplitudes in the classical limit [98–103], and we will reproduce results recently derived from this perspective [102], furthermore calculating the leading angular impulse (i.e. the change in spin during scattering) for the first time.

Our paper is organised as follows. We begin our discussion in the context of electrodynamics, constructing the effective action for a $\sqrt{\text{Kerr}}$ probe in an arbitrary electromagnetic background. In this case it is rather easy to understand how the worldsheet emerges. We discuss key properties of the worldsheet, including the origin of the Newman-Janis shift, in this context. It turns out to be useful to perform the matching in a spacetime with “split” signature $(+, +, -, -)$, largely because the three-point amplitude does not exist on-shell in Minkowski space. The structure of the worldsheet is particularly simple in split-signature spacetimes. In section 3 we turn to the gravitational case, showing that the worldsheet naturally describes the dynamics of a spinning Kerr particle. We discuss equations of motion in section 4, focussing on the leading-order interactions which are not sensitive to terms in the effective action which we have not constrained. In this section, we will see how useful the methods of spinor-helicity are to capture the chiral dynamics associated with the NJ shift, as well as magnetic charges. We finish our paper with a brief discussion.

2 From amplitude to action

We begin our story concentrating on the slightly simpler example of the $\sqrt{\text{Kerr}}$ particle in electromagnetism. We wish to construct an effective action for a massive, charged particle with spin angular momentum $S^{\mu\nu}$. Building on the work of Porto, Rothstein, Levi and Steinhoff [92–94, 96, 104], we write the worldline action as

$$S = \int d\tau \left\{ -m\sqrt{u^2} - \frac{1}{2} S_{\mu\nu} \Omega^{\mu\nu} - QA \cdot u \right\} + S_{\text{EFT}}, \quad (2.1)$$

where u^μ and $\Omega^{\mu\nu}$ are the linear and angular velocities,¹ and S_{EFT} contains additional operators coupling the spinning particle to the electromagnetic field. We will be

¹We will be fixing τ to be the proper time, so the velocity $u^\mu = dr^\mu/d\tau$ will satisfy $u^2 = 1$. The angular velocity can be defined through a body-fixed frame $e_\mu^a(\tau)$ on the worldline as

$$\Omega^{\mu\nu}(\tau) = e_a^\mu(\tau) \frac{d}{d\tau} e^{a\nu}(\tau). \quad (2.2)$$

The tetrad allows us to pass from body-fixed frame indices a, b, \dots to Lorentz indices μ, ν, \dots , as usual. More details on spinning particles in effective theory can be found in recent reviews [105, 106].

assuming the spin tensor to be transverse according to the Tulczyjew covariant spin supplementary condition (SSC)

$$S_{\mu\nu}p^\nu = 0, \quad p_\mu = -\frac{\partial L}{\partial u^\mu} = mu_\mu + \mathcal{O}(A). \quad (2.3)$$

We can therefore relate the spin angular momentum to the spin pseudovector a^μ by

$$a^\mu = \frac{1}{2p^2} \epsilon^{\mu\nu\rho\sigma} p_\nu S_{\rho\sigma} \quad \Leftrightarrow \quad S_{\mu\nu} = \epsilon_{\mu\nu\rho\sigma} p^\rho a^\sigma. \quad (2.4)$$

The effective action (2.1) can be written independently of the choice of SSC, at the expense of introducing an additional term from minimal coupling [95]. This has played an important role in recent work pushing the gravitational effective action beyond linear-in-curvature terms [107–109], but for our present purposes a fixed SSC will suffice. Note that any differences in the choice of the spin tensor $S_{\mu\nu}$ are projected out from the pseudovector a^μ by definition, and it is the latter that will be central to our discussion.

We will only consider the effective operators in S_{EFT} that involve one power of the electromagnetic field A_μ , which can be fixed by the three-point amplitudes. Since these amplitudes are parity-even, the possible single-photon operators are

$$S_{\text{EFT}} = Q \sum_{n=1}^{\infty} \int d\tau u^\mu a^\nu [B_n (a \cdot \partial)^{2n-2} F_{\mu\nu}^*(x) + C_n (a \cdot \partial)^{2n-1} F_{\mu\nu}(x)]_{x=r(\tau)}. \quad (2.5)$$

Notice that an odd number of spin pseudovectors is accompanied by the dual field strength

$$F_{\mu\nu}^* = \frac{1}{2} \epsilon_{\mu\nu\rho\sigma} F^{\rho\sigma}, \quad (2.6)$$

while the plain field strength goes together with an even power of a . By dimensional analysis, the unknown constant coefficients B_n and C_n are dimensionless.

2.1 Worldsheet from source

To determine the unknown coefficients, we choose to match our effective action to a quantity that can be derived directly from the three-point $\sqrt{\text{Kerr}}$ amplitude (1.3). A convenient choice is the Maxwell spinor given by the amplitude for an incoming photon, which is [110]

$$\phi(x) = -\frac{\sqrt{2}}{m} \text{Re} \int d\Phi(k) \hat{\delta}(k \cdot u) |k\rangle \langle k| e^{-ik \cdot x} \mathcal{A}_{3,+}. \quad (2.7)$$

In this expression, the integration is over on-shell massless phase space²

$$d\Phi(k) = \hat{d}^4 k \hat{\delta}(k^2) \Theta(k^0) \equiv \frac{d^4 k}{(2\pi)^4} (2\pi) \hat{\delta}(k^2) \Theta(k^0). \quad (2.8)$$

²Here and below we use the hat notation to absorb appropriate momentum-space factors of 2π .

This Maxwell spinor is defined in (2,2) signature. Indeed, in Minkowski space, the only solution of the zero-energy condition $k \cdot u$ for a massless, on-shell momentum is $k^\mu = 0$, so the three-point amplitude cannot exist on shell for non-trivial kinematics. However, there is no such issue in (2,2) signature, which motivates analytically continuing from Minkowski space. (The spinor $|k\rangle$ is constructed from the on-shell null momentum k as usual in spinor-helicity.)

In fact, the Newman-Janis shift makes it extremely natural for us to analytically continue to split signature even in the classical sense, without any consideration of three-point amplitudes. The Maxwell spinor for a static $\sqrt{\text{Kerr}}$ particle is explicitly

$$\phi^{\sqrt{\text{Kerr}}}(x) = -\frac{Q}{4\pi} \frac{1}{(x^2 + y^2 + (z + ia)^2)^{3/2}} (x, y, z + ia) \cdot \boldsymbol{\sigma}. \quad (2.9)$$

In preparation for the analytic continuation $z = -iz'$, we may choose to order the Pauli matrices as $\boldsymbol{\sigma} = (\sigma_z, \sigma_x, \sigma_y)$. Then the spinor structure in equation (2.9) becomes real, while the radial fall-off factor in the Maxwell spinor simplifies to

$$\frac{1}{(x^2 + y^2 - (z - a)^2)^{3/2}},$$

where we have dropped the prime sign of z . In short, we have a real Maxwell spinor in (2,2) signature, and the spin a is now a real translation in the timelike z direction.

We now analytically continue the action (2.5) by choosing the spin direction to become timelike. In doing so, we also continue the component of the EM field in the spin direction, consistent with a covariant derivative $\partial + iQA$. In split signature, it is convenient to rewrite the effective action ansatz in terms of self- and anti-self-dual field strengths, which we define as

$$F_{\mu\nu}^\pm(x) = F_{\mu\nu}(x) \pm F_{\mu\nu}^*(x). \quad (2.10)$$

Our action then depends on a new set of unknown Wilson coefficients \tilde{B}_n and \tilde{C}_n :

$$S_{\text{EFT}} = Q \sum_{n=0}^{\infty} \int d\tau u^\mu a^\nu [\tilde{B}_n (a \cdot \partial)^n F_{\mu\nu}^+(x) + \tilde{C}_n (a \cdot \partial)^n F_{\mu\nu}^-(x)]_{x=r(\tau)}. \quad (2.11)$$

To determine these coefficients we can match to the three-point amplitude by computing the Maxwell spinor for the radiation field sourced by the $\sqrt{\text{Kerr}}$ particle, which we assume to have constant spin a^μ and constant proper velocity u^μ . In (2,2) signature the exponential factor in eq. (1.3) also picks up a factor i , so we match our action to

$$\phi(x) = -\frac{\sqrt{2}}{m} \text{Re} \int d\Phi(k) \hat{\delta}(k \cdot u) |k\rangle \langle k| e^{-ik \cdot x} \mathcal{A}_{3,+}^{\text{Coulomb}} e^{ik \cdot a}. \quad (2.12)$$

The matching calculation is detailed in appendix A, and determines the Wilson coefficients to be

$$\begin{aligned}
S_{\text{EFT}} &= Q \sum_{n=0}^{\infty} \int d\tau u^\mu a^\nu \left[\frac{(a \cdot \partial)^n}{2(n+1)!} F_{\mu\nu}^+(x) - \frac{(-a \cdot \partial)^n}{2(n+1)!} F_{\mu\nu}^-(x) \right]_{x=r(\tau)} \\
&= \frac{Q}{2} \int d\tau u^\mu a^\nu \left[\frac{e^{a \cdot \partial} - 1}{a \cdot \partial} F_{\mu\nu}^+(x) - \left(\frac{e^{-a \cdot \partial} - 1}{-a \cdot \partial} \right) F_{\mu\nu}^-(x) \right]_{x=r(\tau)}.
\end{aligned} \tag{2.13}$$

So far, the Newman-Janis structure is hinted at by the translation operators $e^{\pm a \cdot \partial}$ appearing in the effective action. We can make this structure more manifest by writing the effective action equivalently as

$$\begin{aligned}
S_{\text{EFT}} &= \frac{Q}{2} \int d\tau \int_0^1 d\lambda u^\mu a^\nu \left[e^{\lambda(a \cdot \partial)} F_{\mu\nu}^+(x) - e^{-\lambda(a \cdot \partial)} F_{\mu\nu}^-(x) \right]_{x=r(\tau)} \\
&= \frac{Q}{2} \int d\tau \int_0^1 d\lambda u^\mu a^\nu \left[F_{\mu\nu}^+(r + \lambda a) - F_{\mu\nu}^-(r - \lambda a) \right].
\end{aligned} \tag{2.14}$$

Our effective action is now an integral over a two-dimensional region — a worldsheet, rather than a worldline.

To see that this worldsheet is indeed connected to the Newman-Janis shift, let us recover this shift for the Maxwell spinor. The gauge field A_μ set up at a point x by the worldsheet source is an integral of a Green's function $G(x - y)$ over the worldsheet. The field strength follows by differentiation, after which contraction with σ matrices yields the Maxwell spinor:

$$\phi(x) = 2Q \int d\tau \sigma_{\mu\nu} u^\nu \partial^\mu \left[G(x - r) + \int_0^1 d\lambda (a \cdot \partial) G(x - r + \lambda a) \right], \tag{2.15}$$

where the first term comes from the non-spinning part of the action (2.1). Now the $a \cdot \partial$ operator acting on the Green's function can be understood as a derivative with respect to λ . This produces a λ integral of a total derivative, which reduces to the boundary terms. Cancelling the first term in eq. (2.15) against the boundary contribution at $\lambda = 0$, we find simply that

$$\phi(x) = 2Q \int d\tau \sigma_{\mu\nu} u^\nu \partial^\mu G(x - r + a). \tag{2.16}$$

The Maxwell spinor depends only on the anti-self-dual part of the effective action, shifted by the spin length. The real translation in (2, 2) signature is a result of this real worldsheet structure. We will shortly see that this structure persists for interactions.

Figure 1. Geometry of the effective action: boundary $\partial\Sigma_n$ of the complex worldsheet (translucent plane) is fixed to the particle worldline in real space (solid plane).

2.2 Worldsheet for interactions

Let us analytically continue the action (2.14) back to Minkowski space:

$$\begin{aligned} S_{\text{EFT}} &= -\frac{Q}{2} \int d\tau \int_0^1 d\lambda u^\mu a^\nu [iF_{\mu\nu}^+(r - i\lambda a) - iF_{\mu\nu}^-(r + i\lambda a)] \\ &= -Q \operatorname{Re} \int_\Sigma d\tau d\lambda iF_{\mu\nu}^+(r - i\lambda a) u^\mu a^\nu. \end{aligned} \quad (2.17)$$

Here the self-dual and anti-self-dual field strengths are

$$F_{\mu\nu}^\pm = F_{\mu\nu} \pm iF_{\mu\nu}^* = \pm \frac{i}{2} \epsilon_{\mu\nu\rho\sigma} F^{\pm\rho\sigma}, \quad (2.18)$$

and $\Sigma = \{\tau \in (-\infty, \infty)\} \times \{\lambda \in [0, 1]\}$ is the worldsheet.

Now that we are back in Minkowski space, let us turn to the Newman-Janis structure of interactions. Suppose that our spinning particle is moving under the influence of an external electromagnetic field, generated by distant sources. The total interaction Lagrangian contains the worldsheet term (2.18) as well as the usual worldline minimal coupling:

$$S_{\text{int}} = -Q \int_{\partial\Sigma_n} d\tau A_\mu(r) u^\mu - Q \operatorname{Re} \int_\Sigma d\tau d\lambda iF_{\mu\nu}^+(r - i\lambda a) u^\mu a^\nu + \dots, \quad (2.19)$$

where $\partial\Sigma_n$ is the “near” boundary of the worldsheet, at $\lambda = 0$, as shown in figure 1. We will similarly refer to the boundary at $\lambda = 1$ as the “far” boundary. The near boundary is the physical location of the object, while the far boundary is a timelike line embedded in the complexification of Minkowski space. We have also indicated the presence of unknown additional operators (involving at least two powers of the field strength) in the action by the ellipsis in eq. (2.19).

It is convenient to introduce a complex coordinate $z = r - i\lambda a$ on the worldsheet. In terms of this coordinate, we may write the two-form

$$F^+(z) = \frac{1}{2} F_{\mu\nu}^+(z) dz^\mu \wedge dz^\nu = -iF_{\mu\nu}^+(z) (u^\mu - i\lambda \dot{a}^\mu) a^\nu d\tau \wedge d\lambda, \quad (2.20)$$

where $\dot{a}^\mu = da^\mu/d\tau$. Since in the absence of interactions the spin is constant, \dot{a} must be of order F . Therefore, we may rewrite our interaction action as

$$S_{\text{int}} = -Q \int_{\partial\Sigma_n} A_\mu(r) dr^\mu + \frac{Q}{2} \text{Re} \int_{\Sigma} F_{\mu\nu}^+(z) dz^\mu \wedge dz^\nu + \dots \quad (2.21)$$

In doing so, we have redefined the higher operators indicated by the ellipsis.

When the electromagnetic fields appearing in the action (2.21) are generated by external sources, both F and F^* are closed two-forms, so we may introduce potentials A and A^* such that $F = dA$ and $F^* = dA^*$. The dual gauge potential A^* is related to A by duality, but this relationship need not concern us here: we only require that both potentials exist in the vicinity of the $\sqrt{\text{Kerr}}$ particle. Hence we may also write $F^+ = dA + i dA^* = dA^+$. Then the action (2.21) becomes

$$\begin{aligned} S_{\text{int}} &= -Q \int_{\partial\Sigma_n} A + Q \text{Re} \int_{\Sigma} dA^+ + \dots \\ &= -Q \int_{\partial\Sigma_n} A + Q \text{Re} \int_{\partial\Sigma_n} A^+ - Q \text{Re} \int_{\partial\Sigma_f} A^+ + \dots, \end{aligned} \quad (2.22)$$

where the boundary consists of two disconnected lines (the far and near boundaries). The orientation of the integration contour was set by F^+ , as depicted in figure 1.

Now, notice that on the near boundary $z = r(\tau)$ is real. Hence $\text{Re} A^+ = A$, so we are only left with the far-boundary contribution in the action:

$$S_{\text{int}} = -Q \text{Re} \int_{\partial\Sigma_f} A^+ + \dots = -Q \text{Re} \int d\tau u^\mu A_\mu^+(r - ia) + \dots \quad (2.23)$$

Thus we explicitly see that the interactions of a $\sqrt{\text{Kerr}}$ particle can be described with a Newman-Janis shift. We will exploit this fact explicitly in section 4. Before we do, we turn to gravitational interactions.

3 Spin and gravitational interactions

As a step towards a worldsheet action for a probe Kerr in a non-trivial background, it is helpful to understand how to make the electromagnetic effective action (2.18) generally covariant. In a curved spacetime, we cannot simply add a vector λa to a point r . To see what to do, let us reintroduce translation operators as in eq. (2.14). The worldsheet EFT term in Minkowski space is

$$\begin{aligned} S_{\text{EFT}} &= -Q \text{Re} \int_{\Sigma} d\tau d\lambda i e^{-i\lambda a \cdot \partial} F_{\mu\nu}^+(x) u^\mu a^\nu \Big|_{x=r(\tau)} \\ &= -Q \text{Re} \int_{\Sigma} d\tau d\lambda i \sum_{n=0}^{\infty} \frac{1}{n!} (-i\lambda a \cdot \partial)^n F_{\mu\nu}^+(x) u^\mu a^\nu \Big|_{x=r(\tau)}. \end{aligned} \quad (3.1)$$

Now it is clear that a minimal way to make this term generally covariant is to replace the partial derivatives ∂ with covariant derivatives ∇ , so in curved space we have

$$S_{\text{EFT}} = -Q \operatorname{Re} \int_{\Sigma} d\tau d\lambda \sum_{n=0}^{\infty} \frac{1}{n!} (-i\lambda a \cdot \nabla)^n F_{\mu\nu}^+(x) iu^\mu a^\nu \Big|_{x=r(\tau)}. \quad (3.2)$$

It is therefore natural for us to consider a covariant translation operator

$$e^{-i\lambda a \cdot \nabla} \equiv \sum_{n=0}^{\infty} \frac{1}{n!} (-i\lambda a \cdot \nabla)^n. \quad (3.3)$$

This operator generates translations along geodesics in the direction a . To see why, note that the perturbative expansion of such a geodesic beginning at a point x_0 in the direction a with parameter ℓ is

$$x^\mu(\ell) = x_0^\mu + \ell a^\mu - \frac{\ell^2}{2} \Gamma_{\nu\rho}^\mu(x_0) a^\nu a^\rho + \dots \quad (3.4)$$

Now consider the perturbative expansion of a scalar function $f(x)$ along such a geodesic. We have

$$\begin{aligned} f(x(\ell)) &= f(x_0) + \ell a \cdot \partial f(x_0) + \frac{\ell^2}{2} a^\mu a^\nu (\partial_\mu \partial_\nu f(x_0) - \Gamma_{\mu\nu}^\alpha(x_0) \partial_\alpha f(x_0)) + \dots \\ &= f(x_0) + \ell a \cdot \nabla f(x_0) + \frac{\ell^2}{2} a \cdot \nabla a \cdot \nabla f(x_0) + \dots \\ &= e^{\ell a \cdot \nabla} f(x_0). \end{aligned} \quad (3.5)$$

A traditional point of view on eq. (3.2) is that the operators only act on the two-form $F_{\mu\nu}^+$. However, we can alternatively think of the operator acting on a scalar function $F_{\mu\nu}^+ u^\mu a^\nu$ provided we extend the definitions of the velocity u and the spin a so that they become fields on the domain of the translation operator. We can simply do this by parallel-transporting $u(r(\tau))$ and $a(r(\tau))$ along the geodesic beginning at $r(\tau)$ in the direction $a(\tau)$ (using the Levi-Civita connection). We denote these geodesics by $z(\tau, \lambda)$; explicitly,

$$z^\mu(\tau, \lambda) = r^\mu(\tau) - i\lambda a^\mu(\tau) + \frac{\lambda^2}{2} \Gamma_{\nu\rho}^\mu(r(\tau)) a^\nu a^\rho + \dots \quad (3.6)$$

(Notice that the translation operator (3.3) has parameter $-i\lambda$.) The parallel-transported vectors, with initial conditions $a(z(\tau, 0)) = a(\tau)$ and $u(z(\tau, 0)) = u(\tau)$, have the similar perturbative expansions

$$\begin{aligned} u^\mu(z(\tau, \lambda)) &= u^\mu(\tau) + i\lambda \Gamma_{\nu\rho}^\mu(r(\tau)) a^\nu(\tau) u^\rho(\tau) + \dots, \\ a^\mu(z(\tau, \lambda)) &= a^\mu(\tau) + i\lambda \Gamma_{\nu\rho}^\mu(r(\tau)) a^\nu(\tau) a^\rho(\tau) + \dots \end{aligned} \quad (3.7)$$

We now view the translation operator in eq. (3.2) as acting on the scalar quantity $F_{\mu\nu}^+ u^\mu a^\nu$:

$$e^{-i\lambda a \cdot \nabla} F_{\mu\nu}(r(\tau)) a^\mu(\tau) u^\nu(\tau) = F_{\mu\nu}(z(\tau, \lambda)) a^\mu(z(\tau, \lambda)) u^\nu(z(\tau, \lambda)). \quad (3.8)$$

Expanding perturbatively to first order in λ , we have

$$\begin{aligned} e^{-i\lambda a \cdot \nabla} F_{\mu\nu}(r(\tau)) a^\mu(\tau) u^\nu(\tau) &= (F_{\mu\nu}(r(\tau)) - i\lambda a^\rho (\partial_\rho F_{\mu\nu} - \Gamma_{\mu\rho}^\alpha F_{\alpha\nu} - \Gamma_{\nu\rho}^\alpha F_{\mu\alpha})) a^\mu u^\nu \\ &= (F_{\mu\nu}(r(\tau)) - i\lambda a^\rho \nabla_\rho F_{\mu\nu}) a^\mu u^\nu. \end{aligned} \quad (3.9)$$

The final expression is precisely the same as the picture in which the derivatives act only on the field strength: these are equivalent points of view.

The worldsheet arises from interpreting the translation operators as genuine translations. In curved space, the operators replace the straight-line sum $r - ia\lambda$ appearing in our action (2.18) with the natural generalisation — a geodesic in the direction a .³ We can express the curved-space effective action as

$$S_{\text{EFT}} = -Q \operatorname{Re} \int_{\Sigma} d\tau d\lambda i F_{\mu\nu}^+(z) u^\mu(z) a^\nu(z) \Big|_{z=z(\tau, \lambda)}. \quad (3.10)$$

The surface Σ is built up from the worldline of the particle, augmented by the geodesics in the direction a for each τ .

Note that, since we neglect higher-order interactions, we may replace the velocity vector field $u(\tau, \lambda)$ in the action (3.10) with the similarly defined momentum field $p(\tau, \lambda)$. Indeed, at $\lambda = 0$ the difference adds another order in the gauge field, as shown in eq. (2.3), and this persists for $\lambda \neq 0$ after parallel translation along the geodesics. Therefore, up to F^2 operators that we are neglecting, the $\sqrt{\text{Kerr}}$ action may be written as

$$S_{\text{EFT}} = -\frac{Q}{m} \operatorname{Re} \int_{\Sigma} d\tau d\lambda i F_{\mu\nu}^+(z) p^\mu(z) a^\nu(z) \Big|_{z=z(\tau, \lambda)}. \quad (3.11)$$

We are now ready for the fully gravitational Kerr worldsheet action, which is naturally motivated as a classical double copy of this covariantised worldsheet action. Recalling that we should double-copy from non-Abelian gauge theory rather than electrodynamics, we promote the field strength to the Yang-Mills case:

$$Q F_{\mu\nu}^+(z) \rightarrow c^A(z) F_{\mu\nu}^{A+}(z), \quad (3.12)$$

where $c^A(z(\tau, \lambda))$ is a vector in the colour space (generated by parallel transport from the classical colour vector of a particle, as described by the Yang-Mills-Wong

³In general, these geodesics may become singular. We assume that such singularities do not arise. If they were to arise, there would also be a divergence in the interpretation of the EFT as an infinite sum of operators.

equations [111]). The double copy replaces colour by kinematics, so we anticipate a replacement of the form $c^A \rightarrow u^\mu$. Moreover, to replace $F_{\mu\nu}^A$ we need an object with three indices, antisymmetric in two of them, for which the spin connection

$$\omega_\mu^{ab} = e_\nu^b \nabla_\mu e^{a\nu} = e_\sigma^b (\partial_\mu e^{a\sigma} + \Gamma_{\mu\nu}^\sigma e^{a\nu}) \quad (3.13)$$

is the natural candidate. Since it is defined via a derivative of the (body-fixed) spacetime tetrad e_a^μ , which is a dimensionless quantity, on dimensional grounds the replacement should be of the form $F_{\mu\nu}^A \rightarrow m\omega_\mu^{ab}$. Indeed, we find that the correct worldsheet action for Kerr is

$$S_{\text{EFT}} = \text{Re} \int_\Sigma d\tau d\lambda i u_\mu(z) \omega^{+\mu}_{ab}(z) p^a(z) a^b(z) \Big|_{z=z(\tau,\lambda)}, \quad (3.14)$$

where ω^+ is a self-dual part of the spin connection, defined explicitly by

$$\omega^{+\mu}_{ab}(x) = \omega^\mu_{ab}(x) + i\omega^{*\mu}_{ab}(x), \quad \omega^{*\mu}_{ab}(x) = \frac{1}{2}\epsilon_{abcd}\omega^{\mu cd}(x). \quad (3.15)$$

In writing these equations, we have extended the body-fixed frame $e_a = e_a^\mu \partial_\mu$ of vectors to every point of the complex worldsheet. We do so by parallel transport. As usual, the frame indices a, b, \dots take values from 0 to 3, and ϵ_{abcd} is the flat-space Levi-Civita tensor, with $\epsilon_{0123} = +1$.

3.1 Flat-space limit

We will shortly prove that the worldsheet term (3.14) reproduces all single-curvature terms in the known effective action for a Kerr black hole in an arbitrary background [93, 94, 96]. But first we wish to show that the term is non-trivial even in flat space, and is in fact the standard kinetic term for a spinning particle in Minkowski space [92] in that context.

In flat space and Cartesian coordinates, the worldsheet effective term (3.14) is

$$S_{\text{EFT}} = \text{Re} \int d\tau \int_0^1 d\lambda i u_\mu(\tau) \omega^{+\mu}_{ab}(r - i\lambda a) p^a(\tau) a^b(\tau), \quad (3.16)$$

since the parallel transport of the vectors u, p and a is now trivial, and the geodesics reduce to straight lines. In flat space, the frame $e_a^\mu(\tau, \lambda)$ is also independent of λ , since it is generated by parallel transport. Thus, the spin connection is λ -independent and the λ integral in eq. (3.16) becomes trivial.

Given the λ independence of the spin connection, we may write

$$\begin{aligned} S_{\text{EFT}} &= \text{Re} \int d\tau \int_0^1 d\lambda i u_\mu(\tau) \omega^{+\mu}_{ab}(r(\tau)) p^a(\tau) a^b(\tau) \\ &= - \int d\tau u_\mu(\tau) \omega^{*\mu}_{ab}(r(\tau)) p^a(\tau) a^b(\tau). \end{aligned} \quad (3.17)$$

Recalling the definitions of the dual spin connection ω^* and the spin pseudovector a , eqs. (3.15) and (2.4), we equivalently have

$$S_{\text{EFT}} = -\frac{1}{2} \int d\tau u_\mu(\tau) \omega^{\mu ab}(r(\tau)) S_{ab}(\tau) = -\frac{1}{2} \int d\tau \Omega^{ab}(r(\tau)) S_{ab}(\tau). \quad (3.18)$$

This is nothing but the spin kinetic term written in eq. (2.1). In this way, we see that the worldsheet expression (3.14) already describes the basic dynamics of spin.

3.2 Single-Riemann effective operators

It is now straightforward to recover the full tower of single-Riemann operators in the Kerr effective action. Returning to the full curved-space case, we may write our action (3.14) as

$$\begin{aligned} S_{\text{EFT}} &= \text{Re} \int d\tau \int_0^1 d\lambda e^{-i\lambda a \cdot \nabla} i u_\mu(\tau) \omega^{+\mu}_{ab}(r(\tau)) p^a(\tau) a^b(\tau) \\ &= \text{Re} \int d\tau i \left(\frac{e^{-ia \cdot \nabla} - 1}{-ia \cdot \nabla} \right) u_\mu(\tau) \omega^{+\mu}_{ab}(r(\tau)) p^a(\tau) a^b(\tau) \\ &= \sum_{n=0}^{\infty} \text{Re} \int d\tau \frac{(-ia \cdot \nabla)^n}{(n+1)!} i u_\mu(\tau) \omega^{+\mu}_{ab}(r(\tau)) p^a(\tau) a^b(\tau), \end{aligned} \quad (3.19)$$

where we performed the λ integral and expanded the translation operator $e^{-ia \cdot \nabla}$. The leading contribution is again the spin kinetic term, as a short computation demonstrates. We also encounter an infinite series of higher-derivative contributions for $n \geq 1$. To express them in terms of the Riemann tensor, we recall that it satisfies

$$R_{ab\mu\nu} = e_a^\alpha e_b^\beta R_{\alpha\beta\mu\nu} = \nabla_\mu \omega_{\nu ab} - \nabla_\nu \omega_{\mu ab} - \omega_{\mu ac} \omega_\nu{}^c{}_b + \omega_{\nu ac} \omega_\mu{}^c{}_b. \quad (3.20)$$

Consistently omitting the quadratic in ω terms from the equation above, as well as the higher-order interaction contributions due to the difference between p^a and mu^a , we rewrite a typical effective operator as

$$\begin{aligned} &\frac{1}{(n+1)!} \text{Re} \int d\tau u^\mu p^a a^b (-ia \cdot \nabla)^{n-1} a^\nu \nabla_\nu \omega_{\mu ab}^+ \Big|_{x=r(\tau)} \\ &= -\frac{1}{(n+1)!} \text{Re} \int d\tau p^a a^b u^\mu a^\nu (-ia \cdot \nabla)^{n-1} [R_{ab\mu\nu}^+ - \nabla_\mu \omega_{\nu ab}^+]_{x=r(\tau)} + \dots \\ &= -\frac{m}{(n+1)!} \text{Re} \int d\tau u^a a^b a^\nu (-ia \cdot \nabla)^{n-1} \left[u^\mu R_{ab\mu\nu}^+ - \frac{D}{d\tau} \omega_{\nu ab}^+ \right]_{x=r(\tau)} + \dots \end{aligned} \quad (3.21)$$

Here $R_{ab\mu\nu}^+ = R_{ab\mu\nu} + iR_{ab\mu\nu}^*$ is defined via the dualisation of the first two indices. Notice that in equation (3.21) we treat the velocity u , momentum p and spin a as fields on the worldline, so that they commute with the covariant derivative.

We may proceed by integrating the $D/d\tau$ term by parts, after which it acts on factors of velocity and spin. This generates curvature-squared (and higher) operators

that we again neglect. In this way, we arrive at the form of the leading interaction Lagrangian

$$S_{\text{int}} = -m \int d\tau u^a a^b u^\mu a^\nu \text{Re} \sum_{n=1}^{\infty} \frac{(-ia \cdot \nabla)^{n-1}}{(n+1)!} \left[R_{ab\mu\nu} + iR_{ab\mu\nu}^* \right]_{x=r(\tau)} + \dots \quad (3.22)$$

Finally, separating the even and odd values of n into two distinct sums

$$S_{\text{int}} = m \int d\tau \left[\sum_{n=1}^{\infty} \frac{(-1)^n}{(2n)!} (a \cdot \nabla)^{2n-2} R_{\alpha\beta\mu\nu} u^\alpha a^\beta u^\mu a^\nu + \sum_{n=1}^{\infty} \frac{(-1)^n}{(2n+1)!} (a \cdot \nabla)^{2n-1} R_{\alpha\beta\mu\nu}^* u^\alpha a^\beta u^\mu a^\nu \right]_{x=r(\tau)} + \dots, \quad (3.23)$$

one can verify that this reproduces the leading interactions of a Kerr black hole, as discussed in detail by Levi and Steinhoff [96].

It is interesting that the worldsheet structure unifies the spin kinetic term with the leading interactions of Kerr. The same phenomenon was observed directly at the level of amplitudes in ref. [25].

4 Spinorial equations of motion

Eq. (2.23) explicitly displays a Newman-Janis shift for the leading interactions of the $\sqrt{\text{Kerr}}$ solution. Now we take a first look at the structure of the equations of motion encoding this shift. Since the Newman-Janis shift is chiral, we will find that it is very convenient to describe the dynamics using the method of spinor-helicity, even in a fully classical setting. Our focus here will be to extract expressions for observables from the equations of motion at leading order. Thus we are free to make field redefinitions, dropping total derivatives which do not contribute to observables. We will also extend our work to magnetically charged objects, such as spinning dyons and the gravitational Kerr-Taub-NUT analogue at the level of equations of motion.

We may write the leading order action for a $\sqrt{\text{Kerr}}$ particle with trajectory $r(\tau)$ and spin $a(\tau)$ as

$$S = - \int d\tau \left(p \cdot \dot{r}(\tau) + \frac{1}{2} \epsilon(p, a, \Omega) + Q \text{Re} u^\mu A_\mu^+(r - ia) \right) + \dots, \quad (4.1)$$

using the short-hand notation

$$\epsilon(p, a, \Omega) = \epsilon_{\mu\nu\rho\sigma} p^\mu a^\nu \Omega^{\rho\sigma}. \quad (4.2)$$

By varying with respect to the position $r(\tau)$ it is easy to determine that

$$\frac{dp^\mu}{d\tau} = Q \text{Re} F^{+\mu\nu}(r - ia) u_\nu + \dots = \frac{Q}{m} \text{Re} F^{+\mu\nu}(r - ia) p_\nu + \dots \quad (4.3)$$

In the second equality, we replaced the velocity $u = \dot{r}$ with the momentum p/m , noting that the difference between the momentum and mu is of order F . To obtain a similar differential equation for the spin a^μ , it is helpful to begin by differentiating $a \cdot p = 0$, finding

$$p_\mu \frac{da^\mu}{d\tau} = p_\mu \operatorname{Re} \frac{Q}{m} F^{+\mu\nu} (r - ia) a_\nu. \quad (4.4)$$

Based on this simple result, it is easy to guess that the spin satisfies

$$\frac{da^\mu}{d\tau} = \frac{Q}{m} \operatorname{Re} F^{+\mu\nu} (r - ia) a_\nu + \dots, \quad (4.5)$$

and indeed a more lengthy calculation using the Lagrangian (4.1) confirms this guess.

Our expressions (4.3) and (4.5) for the momentum and spin have the same basic structure, and are consistent with the requirements that p^2 and a^2 are constant while $a \cdot p = 0$. In the context of scattering amplitudes it has proven to be very convenient to introduce spinor variables describing similar momenta and spins. Notice that there is nothing quantum about using spinor variables for momenta and spin: the momenta of particles in amplitudes need not be small, and the spin can be arbitrarily large. We are simply taking advantage of the availability of spinorial representations of the Lorentz group. A key motivation for introducing spinors in the present context is the chirality structure of eqs. (4.3) and (4.5), which hint at a more basic description using an intrinsically chiral formalism.

Following Arkani-Hamed, Huang and Huang [91] we introduce spinors $|p_I\rangle$ and $|p_I]$ with $I = 1, 2$ so that the momentum vector is

$$p^\mu = \frac{1}{2} \epsilon^{IJ} \langle p_J | \sigma^\mu | p_I \rangle = \frac{1}{2} \langle p^I | \sigma^\mu | p_I \rangle. \quad (4.6)$$

We raise and lower the little-group indices I, J, \dots with two-dimensional Levi-Civita tensors, as usual. The σ^μ matrices are a basis of the Clifford algebra, and we use the common choice

$$\sigma^\mu = (1, \sigma_x, \sigma_y, \sigma_z). \quad (4.7)$$

The little group of a massive momentum is $\text{SO}(3)$, so to construct the spin vector a^μ in terms of spinors we need only form a little-group vector representation from little-group spinors. The vector representation of $\text{SO}(3)$ is the symmetric tensor product of two spinors, so we will need to symmetrise little-group indices. Let a^{IJ} be a constant symmetric two-by-two matrix; then

$$a^\mu = \frac{1}{2} a^{IJ} \langle p_J | \sigma^\mu | p_I \rangle \quad (4.8)$$

is the spin vector. To understand how these expressions work, it may be helpful to work in a Lorentz frame $p^\mu = (\sqrt{p^2}, 0, 0, 0)$. Then the spin is a purely spatial vector, so it is a linear combination of components in the x, y and z directions. Thus there is

a basis of three possible spins. This is reflected in the three independent components of the symmetric two-by-two matrix a^{IJ} . The algebra of the spinors immediately guarantees that the spin a and the momentum p are orthogonal.

Given that we can always reconstruct the momentum and spin from the spinors, all we now need are dynamical equations for the spinors themselves. The leading-order spinorial equations of motion for $\sqrt{\text{Kerr}}$ are

$$\begin{aligned}\frac{d}{d\tau}|p_I\rangle &= \frac{Q}{2m}\phi(r(\tau) - ia(\tau))|p_I\rangle, \\ \frac{d}{d\tau}|p_I] &= \frac{Q}{2m}\tilde{\phi}(r(\tau) + ia(\tau))|p_I].\end{aligned}\tag{4.9}$$

Notice that the evolution of the spinors is directly determined by the Maxwell spinor of whatever background the particle is moving in. The NJ shift indicated explicitly in eqs. (4.9) is an explicit consequence of the shift (2.23) at the level of the effective action. It is straightforward to recover the vectorial equations (4.3) and (4.5) from our spinorial equation using the familiar spinor-helicity methods.

To illustrate the use of spinorial methods, consider scattering two $\sqrt{\text{Kerr}}$ particles off one another. We will compute both the leading impulse Δp_1 and the leading angular impulse Δa_1 on one of the two particles during the scattering event. These observables are easily obtained using the methods of scattering amplitudes [13, 15, 16, 30]; here, spinorial equations of motion render the computation even simpler. We denote the spinor variables for particle 1 by $|1, \tau\rangle$ and $|1, \tau]$, and similarly for particle 2; these spinors are explicitly functions of proper time. In a scattering event we denote the initial spinors as $|1\rangle \equiv |1, -\infty\rangle$ (and similarly for $|1]$.) The final outgoing spinors are then $|1'\rangle \equiv |1, +\infty\rangle$.

The impulses on particle 1 are given in terms of a leading order kick of the spinor $|\Delta 1\rangle \equiv |1, +\infty\rangle - |1, -\infty\rangle$ as

$$\begin{aligned}\Delta p_1 &= 2\epsilon^{IJ} \text{Re} |\Delta 1_J\rangle [1_I|, \\ \Delta a_1 &= 2a_1^{IJ} \text{Re} |\Delta 1_J\rangle [1_I].\end{aligned}\tag{4.10}$$

(Notice that we are representing the impulses here as bispinors.) Thus we simply need to compute the kick suffered by the spinor of particle 1 to determine *both* impulses, in contrast to other methods available (including using amplitudes [16].) By direct integration of the spinorial equation (4.9) we see that this spinorial kick is

$$|\Delta 1_I\rangle = \frac{Q_1}{2m_1} \int_{-\infty}^{\infty} d\tau \phi(r_1 - ia_1) |1_I\rangle.\tag{4.11}$$

At this level of approximation, we may take the trajectory r_1 to be a straight line with constant velocity, and take the spin a_1 to be constant, under the integral. Notice that we evaluate the Maxwell spinor at the shifted position $r_1 - ia_1$ because of the Newman-Janis shift property at the level of interactions.

To perform the integration we need the Maxwell spinor influencing the motion of particle 1. This is the field of the second of our two particles. It is easy to obtain this field — indeed, by the standard Newman-Janis shift of the field set up by particle 2, we need only shift the Coulomb field of a point-like charge. The field is

$$\phi(x) = 2iQ_2 \int \hat{d}^4 k \hat{\delta}(k \cdot u_2) \frac{e^{-ik \cdot (x+ia_2)}}{k^2} \sigma_{\mu\nu} k^\mu u_2^\nu. \quad (4.12)$$

Note the explicit NJ shift by the spin a_2 : this is the shift of the background, in contrast to the shift through a_1 of eq. (4.11). Of course, there is a pleasing symmetry between these shifts. Using the field (4.12) in our expression (4.11) for the change in the spinors of particle 1, we arrive at an integral expression for the spinor kick,

$$|\Delta 1_I\rangle = \frac{iQ_1 Q_2}{2m_1} \int \hat{d}^4 k \hat{\delta}(k \cdot u_1) \hat{\delta}(k \cdot u_2) \frac{e^{-ik \cdot (b-ia_1+ia_2)}}{k^2} k^\mu u_2^\nu \sigma_{\mu\nu} |1_I\rangle, \quad (4.13)$$

where b is the impact parameter. This expression contains complete information about both the linear and angular impulses. For example, substituting into eq. (4.10) we find that the angular impulse is

$$\begin{aligned} \Delta a_1^\mu = \frac{Q_1 Q_2}{m_1} \operatorname{Re} \int \hat{d}^4 k \hat{\delta}(k \cdot u_1) \hat{\delta}(k \cdot u_2) \frac{e^{-ik \cdot (b-ia_1+ia_2)}}{k^2} \\ \times (ia_1 \cdot u_2 k^\mu - ik \cdot a_1 u_2^\mu + \epsilon^\mu(k, a_1, u_2)). \end{aligned} \quad (4.14)$$

Spinorial equations of motion are also available for the leading order interactions of Kerr moving in a gravitational background. They are

$$\begin{aligned} \frac{d}{d\tau} |p_I\rangle &= -\frac{1}{2} u^\mu \omega_\mu (r - ia) |p_I\rangle, \\ \frac{d}{d\tau} [p_I] &= -\frac{1}{2} u^\mu \tilde{\omega}_\mu (r + ia) [p_I], \end{aligned} \quad (4.15)$$

where the spin connection is written in terms of spinors:

$$\omega_\mu |p\rangle = \omega_\mu^{ab} \sigma_{ab} |p\rangle. \quad (4.16)$$

Using these spinorial equations of motion and a brief calculation in exact analogy with our $\sqrt{\text{Kerr}}$ discussion above, it is straightforward to recover the leading linear and angular impulse due to Kerr/Kerr scattering [112].

In fact we can go further and consider the generalisation of Kerr with NUT charge, corresponding in the stationary case to the Kerr-Taub-NUT solution. It is known that NUT charge can be introduced by performing the gravitational analogue of electric/magnetic duality [97]. Working at linearised level, this deforms the linearised spinorial equation of motion to

$$\begin{aligned} \frac{d}{d\tau} |p_I\rangle &= -\frac{e^{-i\theta}}{2} u^\mu \omega_\mu (r - ia) |p_I\rangle, \\ \frac{d}{d\tau} [p_I] &= -\frac{e^{+i\theta}}{2} u^\mu \tilde{\omega}_\mu (r + ia) [p_I], \end{aligned} \quad (4.17)$$

where θ is a magnetic angle. The particle described by these equations has mass $m \cos \theta$ and NUT parameter $m \sin \theta$. Using these equations, and defining the rapidity w by $\cosh w = u_1 \cdot u_2$, we find that the leading order impulse in a Kerr-Taub-NUT/Kerr-Taub-NUT scattering event is given by

$$\Delta p_1^\mu = 4\pi G m_1 m_2 \operatorname{Re} \int \hat{d}^4 k \hat{\delta}(k \cdot u_1) \hat{\delta}(k \cdot u_2) \frac{e^{-ik \cdot (b - ia_1 + ia_2)}}{k^2} e^{i(\theta_2 - \theta_1)} \times (i \cosh 2w k^\mu + 2 \cosh w \epsilon^\mu(k, u_1, u_2)) , \quad (4.18)$$

in agreement with a previous computation performed using scattering amplitudes [102]. It is also straightforward to compute the angular impulse using these methods; we find that

$$\Delta a_1^\mu = -4\pi G m_2 \operatorname{Re} \int \hat{d}^4 k \hat{\delta}(k \cdot u_1) \hat{\delta}(k \cdot u_2) \frac{e^{-ik \cdot (b - ia_1 + ia_2)}}{k^2} e^{i(\theta_2 - \theta_1)} \times \left(i \cosh 2w \epsilon^\mu(k, u_1, a_1) - 2 \cosh w u_1^\mu \epsilon^\mu(k, u_1, u_2, a_1) - 2ia_1 \cdot u_2 \cosh w k^\mu + ik \cdot a_1 (2 \cosh w u_2^\mu - u_1^\mu) \right) . \quad (4.19)$$

5 Discussion

The Newman-Janis shift is often dismissed as a trick, without any underlying geometric justification. The central theme of our paper is that we should rather view Newman and Janis’s work as an important insight. The Kerr solution is simpler than it first seems, and correspondingly the leading interactions of Kerr are simpler than they might otherwise be. It seems appropriate to place the NJ shift at the heart of our formalism for describing the dynamics of Kerr black holes, thereby taking maximum advantage of this leading order simplicity.

Our spinorial approach to the classical dynamics of Kerr (and its electromagnetic single-copy, $\sqrt{\text{Kerr}}$) makes it trivial to include the spin (to all orders in a) in scattering processes. Computing the evolution of the spinors rather than the momenta and spin separately reduces the workload in performing these computations, and is even more efficient in some examples than computing with the help of scattering amplitudes. However, we only developed these equations at leading order. At higher orders, spinor equations of motion will certainly exist and be worthy of study.

We found that the effective action for Kerr has the surprising property that it can be formulated in terms of a two-dimensional worldsheet integral instead of the usual one-dimensional worldline effective theory. This remarkable fact provides some kind of geometric basis for the Newman-Janis shift, where it emerges using Stokes’s theorem. Our worldsheet actions contain terms integrated over some boundaries, and other terms integrated over the “bulk” two-dimensional worldsheet. This structure is also familiar from brane world scenarios, but is obviously surprising in the

context of Kerr black holes. In Minkowski space, this worldsheet is embedded in a complexification of spacetime, in a manner somewhat reminiscent of other work on complexified worldlines; see ref. [113], for example. However, our worldsheet seems to be a bit of a different beast: it is not a complex line, but rather a strip with two boundaries.

The worldsheet emerged in our work, built up from the physical boundary worldline and geodesics in the direction of spin. This construction is very different from the sigma models familiar from string theory. The dynamical variables in our action are the “near” worldsheet coordinates, the spin, and body-fixed frame. But perhaps these dynamical variables emerge from a geometric description more reminiscent of the picture for strings.

We do not know whether the worldsheet structure persists when higher-order operators, involving two or more powers of the Riemann curvature (or electromagnetic field strength), are included. But we can certainly hope that the surprising simplicity of Kerr persists to higher orders — the computation of observables from loop-level amplitudes for particles with spin [24, 25, 40, 71] certainly indicates that further progress can be made. Meanwhile precision calculations reliant on the effective action in (2.1) require including higher-dimension operators in the action [107–109]. It would be particularly interesting to investigate the symmetry structure of the Kerr worldsheet, with an eye towards placing symmetry constraints on the tower of possible higher-dimension operators.

Our work has touched on a family of solutions including Kerr and its magnetically charged analogue, Kerr-Taub-NUT, as well as a set of related electromagnetic solutions. Taken together the parameters we have introduced number five: electric and magnetic charge, mass and NUT parameter, and spin. These are most, but not all, of the parameters of the famous Plebanski-Demianski family [114, 115] of solutions, which also includes a cosmological constant as well as an acceleration parameter. It would be interesting to see if our methods can be generalised to include the remaining parameters.

We hope that our work is only the beginning of a programme to exploit the Newman-Janis structure of Kerr black holes to simplify their dynamics.

A Split-signature matching calculation

Here we provide further details of the matching calculation which determined the $\sqrt{\text{Kerr}}$ effective action Wilson coefficients in eq. (2.11). We will work exclusively in split signature, for which we adopt the conventions of [110].

Our calculation hinges upon the field strength sourced by the particle, which is determined by the $\sqrt{\text{Kerr}}$ worldline current $\tilde{j}^\mu(k)$. We assume that the particle has constant spin a^μ and constant proper velocity u^μ . In solving the Maxwell equation we impose retarded boundary conditions precisely as in [110], placing our observation point x in the future with respect to one time coordinate t^0 , but choosing the proper velocity u to point along the orthogonal time direction. It is useful to make use of the result

$$\frac{1}{k_{\text{ret}}^2} = -i \text{sign } k^0 \hat{\delta}(k^2) + \frac{1}{k_{\text{adv}}^2}, \quad (\text{A.1})$$

where the ret and adv subscripts indicate retarded and advanced Green's functions, respectively. Since the advanced Green's function has support for $t^0 < 0$, we may simply replace

$$\frac{1}{k_{\text{ret}}^2} = -i \text{sign}(k^0) \hat{\delta}(k^2). \quad (\text{A.2})$$

The field strength sourced by the current in split signature is therefore

$$\begin{aligned} F^{\mu\nu}(x) &= \int \hat{d}^4 k \text{sign}(k^0) \hat{\delta}(k^2) k^{[\mu} \tilde{j}^{\nu]} e^{-ik \cdot x} \\ &= \int \hat{d}^4 k (\Theta(k^0) - \Theta(-k^0)) \hat{\delta}(k^2) k^{[\mu} \tilde{j}^{\nu]} e^{-ik \cdot x}, \end{aligned} \quad (\text{A.3})$$

where our convention for index antisymmetrisation includes no numerical factors. Notice that the appropriate integral measure is now precisely the invariant phase-space measure (2.8); substituting the worldline current for our $\sqrt{\text{Kerr}}$ effective action in eq. (2.11), evaluated on a leading-order trajectory, we thus have

$$\begin{aligned} F^{\mu\nu}(x) &= 2Q \text{Re} \int d\Phi(k) \hat{\delta}(k \cdot u) \left\{ k^{[\mu} u^{\nu]} \left[1 + ia \cdot k \sum_{n=0}^{\infty} \left(\tilde{B}_n(-ia \cdot k)^n + \tilde{C}_n(-ia \cdot k)^n \right) \right] \right. \\ &\quad \left. + ik^{[\mu} \epsilon^{\nu]}(k, u, a) \sum_{n=0}^{\infty} \left(\tilde{B}_n(-ia \cdot k)^n - \tilde{C}_n(-ia \cdot k)^n \right) \right\} e^{-ik \cdot x}. \end{aligned} \quad (\text{A.4})$$

To match to the three-point $\sqrt{\text{Kerr}}$ amplitude, we need to compute the Maxwell spinor ϕ and its conjugate, $\tilde{\phi}$. To do so, we introduce a basis of positive and negative helicity polarisation vectors ε_k^\pm . On the support of the delta function in (A.4), manipulations using the spinorial form of the polarisation vectors given in [110] then lead to

$$\begin{aligned} k^{[\mu} u^{\nu]} \sigma_{\mu\nu} &= +\sqrt{2} \varepsilon_k^+ \cdot u |k\rangle \langle k| \\ k^{[\mu} \epsilon^{\nu]}(k, u, a) \sigma_{\mu\nu} &= -\sqrt{2} a \cdot k \varepsilon_k^+ \cdot u |k\rangle \langle k|. \end{aligned} \quad (\text{A.5})$$

The latter equality relies upon the identity $k^{[\mu}\epsilon^{\nu\rho\sigma\lambda]} = 0$, and the fact that $\sigma_{\mu\nu}$ is self-dual in this signature. With these expressions in hand, it is easy to see that the Maxwell spinor has a common spinorial basis, and takes the simple form

$$\begin{aligned} \phi(x) = 2\sqrt{2}Q \operatorname{Re} \int d\Phi(k) \hat{\delta}(k \cdot u) e^{-ik \cdot x} |k\rangle \langle k| \varepsilon_k^+ \cdot u \\ \times \left(1 + \sum_{n=0}^{\infty} 2\tilde{C}_n (-ia \cdot k)^{n+1} \right). \end{aligned} \quad (\text{A.6})$$

Recall from eq. (2.11) that the Wilson coefficients \tilde{B}_n and \tilde{C}_n were identified with self- and anti-self-dual field strengths, respectively. Since a positive-helicity wave is associated with an anti-self-dual field strength, it is no surprise that the Maxwell spinor should depend only on this part of the $\sqrt{\text{Kerr}}$ effective action. Fixing the \tilde{B}_n coefficients requires the dual spinor, which is given by

$$\begin{aligned} \tilde{\phi}(x) = -2\sqrt{2}Q \operatorname{Re} \int d\Phi(k) \hat{\delta}(k \cdot u) e^{-ik \cdot x} |k] [k| \varepsilon_k^- \cdot u \\ \times \left(1 + \sum_{n=0}^{\infty} 2\tilde{B}_n (-ia \cdot k)^{n+1} \right). \end{aligned} \quad (\text{A.7})$$

Here we have used that

$$\begin{aligned} k^{[\mu} u^{\nu]} \tilde{\sigma}_{\mu\nu} &= -\sqrt{2} \varepsilon_k^- \cdot u |k] [k| \\ k^{[\mu} \epsilon^{\nu]}(k, u, a) \tilde{\sigma}_{\mu\nu} &= -\sqrt{2} a \cdot k \varepsilon_k^- \cdot u |k] [k|, \end{aligned} \quad (\text{A.8})$$

recalling that $\tilde{\sigma}$ is anti-self-dual in split signature spacetimes.

It now only remains to match to the Maxwell spinors for the three-point amplitude, as given in eq. (2.12). The scalar Coulomb amplitudes for photon absorption are just $\mathcal{A}_{\pm} = -2mQ u \cdot \varepsilon_k^{\pm}$, so for the $\sqrt{\text{Kerr}}$ three-point amplitude

$$\begin{aligned} \phi(x) &= +2\sqrt{2}Q \operatorname{Re} \int d\Phi(k) \hat{\delta}(k \cdot u) e^{-ik \cdot x} |k\rangle \langle k| \varepsilon_k^+ \cdot u e^{ik \cdot a}, \\ \tilde{\phi}(x) &= -2\sqrt{2}Q \operatorname{Re} \int d\Phi(k) \hat{\delta}(k \cdot u) e^{-ik \cdot x} |k] [k| \varepsilon_k^- \cdot u e^{-ik \cdot a}. \end{aligned} \quad (\text{A.9})$$

Expanding the exponentials and matching to eqs. (A.6) and (A.7) then yields

$$\tilde{B}_n = \frac{1}{2(n+1)!}, \quad \tilde{C}_n = \frac{(-1)^{n+1}}{2(n+1)!}, \quad (\text{A.10})$$

which are the Wilson coefficients listed in eq. (2.13).
