4.2 Supplementary Figures. ..... 21
Supplementary Figure 1. A schematic representation of the experimental setup. The Speaker (participant) is seated at a table, with the Addressee either sitting side-by-side, or opposite the speaker.Color-coded locations mark distance increases of 25 cm each. In the schematic, three conceptual regionsare represented, such that Region 1 and Region 2, are just as far from the speaker as respectively Region3 and Region 2 are from the Addressee, when seated opposite21

## Supplementary Text

1．Demonstratives Systems for Individual Languages and Term Selection
Below we briefly present the demonstrative systems for each language tested，together with the usual gloss for specific terms（e．g．，proximal，distal）．These glosses come with two important caveats．First， they are in most cases not based on empirical evidence，and when they are，the studies concerned are often underpowered（e．g．，employing ethnographic methods with only a few participants）． Therefore the glosses are subject to testing／confirmation／falsification．Second，for the languages where there is literature discussing the demonstrative system，there is often debate regarding the use of specific terms，and therefore how they are glossed．For each language we label terms＇ 3 rd term＇，＇4 ${ }^{\text {th }}$ term＇，etc．，if there is no consensus in the literature regarding a single gloss．（Notes：Noun position is presented with an＇ N ＇in the individual language overviews；if a language is inflected for number and case we give the singular nominative（or absolutive）form in the tables．）

Arabic（Tunisian）
Tunisian Arabic has three demonstratives inflected for number and gender（S5）．When used as demonstrative pronouns they stand alone as subjects．When they serve as articles，they can appear either before or after the noun．

|  | PROXIMAL | DISTAL | DISTAL |
| :---: | :---: | :---: | :---: |
| MASCULINE | hāđa（ هذا） | hāka（هاكا） | hāđāka（هذاك） |
| FEMININE | hāđi（هذي） | hākī（هاكي） | hāđīka（هذيك） |

## Basque

Basque has three demonstratives inflected for number and case．Adnominal demonstratives have the same forms as demonstrative pronouns and follow the noun．According to Hualde and Ortiz de Urbina （2003；S2），the middle term hori indicates＂proximity to the addressee＂，but in other sources hori is said to indicate a referent in intermediate distance between＇proximal＇hau and＇distal＇hura．

|  | PROXIMAL | $3^{\text {RD }}$ TERM | DISTAL |
| :--- | :--- | :--- | :--- |
| NO GENDER | N hau | N hori | N hura |

## Bulgarian

Bulgarian has proximal and distal demonstratives inflected for gender and number（S3）．The proximal term serves as the default in non－contrastive uses．Adnominal demonstratives have the same forms as demonstrative pronouns and precede the noun．

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| MASCULINE | този／тоя N | онзи／оня N |
| FEMININE | тази／тая N | онази／оная N |
| NEUTER | това／туй N | онова／онуй N |

## Cantonese

Cantonese employs the demonstrative forms $n \overline{1}$＇this＇and $g o$＇that＇，which are generally accompanied by a classifier and optionally by the linking element go（as in Mandarin zhège and nàgè）（S4）．

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| NO GENDER | $n \bar{r}^{2} g o^{3}$（這個）N | $g o^{2} g o^{3}$（那個） N |

Note：Superscript numbers refer to tone．

## Castilian (Spanish)

Castilian has three demonstrative forms inflected for gender and number (S5). Adnominal demonstratives have the same forms as demonstrative pronouns. There is continued debate regarding whether the system is person-centered, distance-based, or a combination of the two (34,39, 47, S5).

|  | PROXIMAL | $3^{\text {RD }}$ TERM | DISTAL |
| :--- | :--- | :--- | :--- |
| MASCULINE | este N | ese N | aque/ N |
| FEMININE | esta N | esa N | aquella N |

Catalan
Catalan has a three-term deictic system (S6), similar to Castilian, but in some current varieties of Catalan the three-term contrast has been reduced to a binary opposition. Adnominal demonstratives are inflected for gender and number. They have the same forms as demonstrative pronouns.

|  | PROXIMAL | $3^{\text {RD }}$ TERM | DISTAL |
| :--- | :--- | :--- | :--- |
| MASCULINE | aquest N | aqueix_N | aquell N |
| FEMININE | aquesta N | aqueixa N | aquella N |

## Danish

Danish has two sets of demonstratives: The archaic simple demonstratives denne/dette 'this', almost exclusively used in written language, and hin, 'that' which has fallen out of use, plus the spatially unmarked pronominal den/det. In spoken language, the complex demonstratives den/det her 'this' and den/det der 'that' are used (S7). The latter consist of the unmarked simple demonstratives den/det and the adverbial demonstratives her/der 'here/there'. The unmarked demonstratives indicate gender and number and precede the noun they modify, while the adverbial part may either precede or succeed the noun. In the experiment, participants used the complex demonstratives.

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| COMMON GENDER | denne / den her N | $\operatorname{den} / \operatorname{den} \operatorname{der} \mathrm{N}$ |
| NEUTER | dette / det her N | $\operatorname{det} / \operatorname{det} \operatorname{der} \mathrm{N}$ |

## Dutch

Dutch has proximal and distal demonstratives inflected for gender and number (S8). Adnominal demonstratives precede the noun and have the same forms as demonstrative pronouns.

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| COMMON GENDER | $\operatorname{deze} \mathrm{N}$ | $\operatorname{die} \mathrm{N}$ |
| NEUTER | $\operatorname{dit} \mathrm{N}$ | $\operatorname{dat} \mathrm{N}$ |

## English

The English demonstratives are inflected for number and precede the noun they modify (S9).
Adnominal demonstratives can also be used as independent pronouns but are combined with the dummy pronoun one in many contexts.

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| NO GENDER | this N | that N |

## Estonian

Different varieties of Estonian have different deictic systems (S10). In the variety tested in this study, speakers use a two-way deictic system with proximal see and distal too. Demonstratives are inflected for number and case and precede the noun they modify.

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| NO GENDER | see N | too N |

Finnish
Finnish has two demonstrative forms inflected for number and case. Adnominal demonstratives precede the noun they modify and have the same forms as demonstrative pronouns. Some older studies mention a second distal term (i.e. se), but a number of recent studies have shown that se serves primarily as a definiteness marker (similar to English the) (S11).

|  | PROXIMAL | DISTAL | $3^{\text {RD }}$ TERM |
| :--- | :--- | :--- | :--- |
| NO GENDER | tämä N | tuo N | se N |

## Georgian

Georgian has three demonstratives that are inflected for number and case when used as independent pronouns (S12). Adnominal demonstratives do not indicate number and distinguish only two cases, i.e. nominative and non-nominative case. Demonstratives precede the noun they modify.

|  | NEAR SPEAKER | NEAR ADDRESSEE | DISTAL |
| :--- | :--- | :--- | :--- |
| NO GENDER | es $(\mathrm{gb}) \mathrm{N}$ | eg (oる) N | is (ob) N |

## German

There is an archaic distinction between proximal dieser 'this.MASC' and distal jener 'that.MASC', but the distal form jener is no longer used with exophoric reference (16). Instead, dieser and the stressed forms of der/die/das are commonly combined with the adverbial demonstratives hier, da and dort (to indicate distance). There is a clear contrast between proximal hier and distal da/dort, but the semantic difference between da and dort is not fully understood (dort is more formal than da). To explore the full extent of the German system, we allowed participants to use hier, da, and dort, and therefore we treated German as a 3-term demonstrative system in our analysis.

|  | PROXIMAL | DISTAL | DISTAL |
| :--- | :--- | :--- | :--- |
| MASCULINE | $\operatorname{der} \mathrm{N}$ hier | $\operatorname{der} \mathrm{N}$ da | $\operatorname{der} \mathrm{N}$ dort |
| FEMININE | die N hier | $\operatorname{die} \mathrm{N}$ da | die N dort |
| NEUTER | das N hier | das N da | das N dort |

Italian
Italian has two demonstrative forms inflected for number and gender (S13). Adnominal demonstratives have the same forms as demonstrative pronouns and precede the noun they modify.

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| MASCULINE | questo N | quello N |
| FEMININE | questa N | quella N |

Japanese
Japanese has three demonstrative determiners that precede the noun they modify．Demonstrative pronouns include the same deictic roots as demonstrative determiners（i．e．ko－，so－，a－），but adnominal and pronominal demonstratives are formally distinguished．There is general consensus that kono marks a referent＇s location near the speaker，while ano marks an object distal to the speaker，but there is considerable debate regarding whether sono is a medial term or alternatively marks the territory near a hearer（38）．

|  | PROXIMAL | $3^{\text {2DD }}$ TERM | DISTAL |
| :--- | :--- | :--- | :--- |
| NO GENDER | kono（この） N | sono（その） N | ano（あの） N |

## Korean

Korean has three deictic particles with a particular term for referents near the addressee：i＇near speaker＇，geu＇near addressee＇，jeo＇away from speaker and addressee＇（S14）．As demonstratives，the three particles are generally followed by a nominal expression，either a noun or another classifier， e．g．，Jeu geot＇that thing＇．The latter type of expressions are functionally equivalent to demonstrative pronouns in other languages．Geu is frequently used for anaphoric reference and can occur without a co－occurring nominal，but in this use Geu functions as a third person pronoun rather than a demonstrative．

|  | NEAR SPEAKER | NEAR ADDRESSEE | DISTAL |
| :--- | :--- | :--- | :--- |
| NO GENDER | $i$（geot）（이）N | geu（geot）（ユ） N | jeo （geot）（저）N |

Latvian
Latvian has two demonstratives inflected for gender，number and case（S15）－tas／tā，šis／šī，tāds／tāda， šāds／šāda－that can be used pronominally or adnominally．Adnominal demonstratives precede the noun they modify and have the same forms as demonstrative pronouns．Šis／šī，šāds／s̄āda are used for referents near the speaker while tas／tā，tāds／tāda－for distant referents．Šis／šĭ，tas／tā are used to refer to objects while šāds／šāda，tāds／tāda－to the properties of objects．In the present experimental setting and semantic context，the near／distant pairs šis／šī and tas／tā will be tested．

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| MASCULINE | šis N | $\operatorname{tas} \mathrm{N}$ |
| FEMININE | ši N | $\operatorname{ta} \mathrm{N}$ |

## Lithuanian

Lithuanian has four demonstrative forms inflected for gender，number and case，which precede the noun they modify．The adnominal demonstratives are also used as independent pronouns：tas－most frequently，šis／šitas－less frequently，but anas－quite rarely．However，šis and šitas are semantically treated as one（etymologically šitas is a compound based on šis and tas）．Traditionally， there is general consensus that šis and šitas are used for referents near the speaker and anas refers to referents that are far away，but tas has been interpreted as distance－neutral．However，more recently it has been suggested that tas should be treated as the main distal demonstrative since anas is not frequently used any more（S16）．Given the fact that šis and šitas are semantically treated as one，we analyzed Lithuanian as a 3 －term demonstrative system．

|  | PROXIMAL | DISTAL TERM | $3^{\text {RD }}$ TERM |
| :--- | :--- | :--- | :--- |
| MASCULINE | šìs／šìtas N | tàs N | anàs N |
| FEMININE | šì／šità N | tà N | anà N |

Maltese
Maltese has proximal and distal demonstratives inflected for gender and number（S17）．The same demonstratives are used as pronouns and as noun modifiers．Adnominal demonstratives precede the noun they modify．

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| MASCULINE | $\operatorname{dan} \mathrm{N}$ | $\operatorname{dak} \mathrm{N}$ |
| FEMININE | $\operatorname{din} \mathrm{N}$ | $\operatorname{dik} \mathrm{N}$ |

## Mandarin

Mandarin demonstratives consist of the deictic elements zhè＇this＇and nà＇that＇and the classifiers ge in singular and xiē in plural．The distal demonstrative nà－gè is frequently used with endophoric reference similar to a definite article．Demonstratives precede the noun they modify and can also be used without a co－occurring noun as independent pronouns（S18）．

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| NO GENDER | zhè－ge（这个）N | nà－gè（那个）N |

## Marathi

Marathi has two demonstrative forms inflected for gender and number．Adnominal demonstratives precede the noun and can also be used as independent pronouns（S19）．

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| MASCULINE | to（तो） N | ha（हा） N |
| FEMININE | $t i$（ती） N | $h i$（ही） N |
| NEUTER | $t e$（ते） N | $h e$（हे） N |

## Nepali

Nepali has two demonstratives inflected for number（S20）．Adnominal demonstratives precede the noun and can also be used as independent pronouns．

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| NO GENDER | yo（यो） N | tyo（त्यो） N |

## Norwegian

Demonstratives are inflected for gender and number and precede the noun they modify．The same demonstratives are used as noun modifiers and independent pronouns．Like Danish，Norwegian has both simple and complex demonstratives．The simple demonstratives occur in Standard Norwegian， but the complex forms are also widely used，especially in spoken registers．According to Vindenes （S21），there is no clear－cut distinction between demonstratives，third person pronouns and definite articles．Usually，definiteness is indicated by bound articles on the noun and discourse participants are tracked by third person pronouns，but the demonstratives are also often used as definite markers and anaphors．

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| COMMON GENDER | denne／den her N | den／den der N |
| NEUTER | dette／det her N | $\operatorname{det} / \operatorname{den} \operatorname{der} \mathrm{N}$ |

Telugu
There are two invariable demonstratives that precede the noun they modify (S22). Unlike adnominal demonstratives, demonstrative pronouns are inflected for gender and number, but include the same deictic roots.

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| NO GENDER | $\bar{i}:(\forall) \mathrm{N}$ | $\bar{a}:(ఆ) \mathrm{N}$ |

## Tseltal

The Tseltal has two demonstratives that act as circumclitics (S23). The two pieces of the demonstrative surround the phrase they are modifying. There is a two-way distinction in Tseltal, proximal and distal (with a third, far distal, possible in the adverbial form of the demonstrative).

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| NO GENDER | in $\mathrm{N} i$ | men Ne |

## Turkish

Turkish has a three-way demonstrative system. The system has been variously described as distance based (proximal, distal, medial) or person-centered. More recently the $3^{\text {rd }}$ term, şu, has been proposed as an attention shifting term, used when the addressee is not attentionally engaged (46). Adnominal demonstratives are uninflected particles that precede the noun, whereas demonstrative pronouns are inflected for number and case.

|  | PROXIMAL | DISTAL | $3^{\text {RD }}$ TERM |
| :--- | :--- | :--- | :--- |
| NO GENDER | $b u \mathrm{~N}$ | oN | şu N |

## Vietnamese

Most studies assume that Vietnamese has a three-way deictic system, but the semantic and pragmatic uses of the three demonstratives is debated. Bui (2014: 47; S24) argues that the distinction between đấy (allomorph đó) and kia does not primarily concern distance but newness: đấy indicates a referent that is known to the hearer, whereas kia is used for newly introduced referents. In addition, there is a demonstrative for invisible referents (i.e. nọ). The non-proximal demonstratives đấy (đó) and kia are also used as independent pronouns, but the proximal term is different. The adnominal demonstratives are invariable particles that follow a noun (which may be accompanied by a classifier). In our study, participants were allowed to use any of 5 demonstratives (Này, Đấy/Đó, kia, plus a distal no, and a proximal đây), in order to explore the full extent of Vietnamese demonstrative use. However, since the frequency of use of no (only 3 uses in Region 2; 4 in Region 3) and đây (15 uses in Region $1 ; 1$ use in Region 2) were so low, we did not include these in our analysis.

|  | PROXIMAL | DISTAL | $3^{\text {RD }}$ TERM | $4^{\text {TH }}$ TERM | $5^{\text {TH }}$ TERM |
| :--- | :--- | :--- | :--- | :--- | :--- |
| NO GENDER | N này | N đấy (đó) | N kia | N nọ | N đây |

## Võro

Võro is closely related to Estonian, but in contrast to Estonian, Võro has three rather than two demonstratives. Traditionally, the medial term taa is considered to indicate a referent near the addressee, but more recently Pajusalu (2015: 18; S25) has argued that taa and tuu differ mainly with regard to accessibility. All three demonstratives can be used as noun modifiers and pronouns, but tuu is primarily a determiner, whereas taa is more frequent as a pronoun. All three demonstratives are inflected for number and case and precede the noun they modify.

|  | PROXIMAL | NEAR ADDRESSEE | DISTAL |
| :--- | :--- | :--- | :--- |
| NO GENDER | sjoo $($ seo $) \mathrm{N}$ | taa N | tuu N |

## Yucatec

The Yucatec demonstratives have unusual syntactic properties as they consist of two discontinuous elements: a determiner (or adverb) that occurs inside the clause and a deictic particle clitic that is attached to the clause-final word (27). Therefore, demonstratives are arguably not a lexical category, but as they still form a binary contrast of exophoric reference of proximal vs. non-proximal, this does not affect our analysis. The determiner le does not indicate any sense of distance or accessibility, but the clause-final deictic clitic particles are contrastive: the "immediate" particle $=a$ ' indicates a referent that is easily accessible to the interlocutors, or in the domain of manipulable space, and that is preferred for referents in the speaker's reach or proximity, and the "non-immediate" particle $=0$ ' indicates a referent that is accessible but without expressing proximity. Crucially, the non-immediate particle serves as a default of sorts, in the sense that it is also commonly used for anaphoric reference and definiteness marking.

It is grammatically sound to combine the proximal and non-proximal terms in a single sentence in reference to the same object. A priori we decided to treat such combinations as a third response option. However, throughout the trials, this option was used only 3 times (2 times in Region 1, 1 time in Region 2), so these trials were excluded from the analysis.

|  | PROXIMAL | DISTAL |
| :--- | :--- | :--- |
| NO GENDER | le $\mathrm{N} \ldots=a^{\prime}$ | le $\mathrm{N} \ldots=o^{\prime}$ |

## 2. Participants and background information

All participants were native speakers (L1 speakers from birth) of the languages tested, with normal or corrected to normal vision (self-report). Most of the participants were bilingual, as would be expected given the languages tested. We also administered a bilingualism questionnaire (S26) to potentially assess language dominance for applicable languages but given that all participants were L1 speakers from birth we do not report these data here. An equal number of male and female participants (selfreported by participants) were recruited (where possible) across languages.

## 3. Secondary Data Analyses

For three of languages - Catalan, Estonian, Võro - data were collected using the protocols set out above, but earlier analyses (using different statistical techniques) have been published in two manuscripts (publications required for PhD theses):

Reile, M., Plado, H., Gudde, H. B., \& Coventry, K. R. (2020). Demonstratives as spatial deictics or something more? Evidence from Common Estonian and Võro. Folia Linguistica, 54 (1).

Todisco, E., Guijarro-Fuentes, P., \& Coventry, K. R. (2021). Analogical levelling in the Majorcan Catalan demonstrative system. Probus: International Journal of Latin and Romance Linguistics, 33(1), 33-56.

Therefore, the analyses presented here are (technically) secondary data analyses for the three languages.

## 4. Supplementary Results

### 4.1 Main Analyses - Additional Information

For the main analyses the decision as to which term is proximal etc. in each language for the analysis was taken a priori based on the linguistic analyses provided above (see also Supplementary Table 2).

In the main analyses reported in the main manuscript both participants and language were included as random effects, and the results are shown in Supplementary Table 3.

### 4.1.1 Interrogating the main effect of distance

The main effect of distance in the main analyses is consistent with a distance function that distinguishes between peripersonal/reachable and extrapersonal/non-reachable space. However, one might argue that the pattern is also consistent with a less specific distance function where participants across all languages merely scale demonstrative choice non-linearly. While one cannot completely rule out that possibility, there are four reasons why a reachable/non-reachable distinction maps most closely onto the data, as follows:

## A) Processing of space is not just distance based

Using language to describe object location first requires processing of space to determine where objects are located (and to prepare for action). It has been established that spatial terms do involve the activation of non-linguistic regions of the brain involved in processing space when comprehending spatial prepositions (S27, S28) or spatial demonstratives (S29). Moreover, it is well established that space is processed not by a single brain system, but in a differentiated manner related to perception and action (see S30, S31 for recent reviews). Studies from single cell recordings with monkeys (e.g. S32, S33), imaging studies with humans (e.g. S34, S35) and studies from patients with specific brain lesions (e.g. S36, S37, S38) have shown a dissociation between peripersonal and extrapersonal space processing. For example, Berti and Frasinetti (S38) reported the case of a patient with visual neglect who exhibited neglect on a line bisection task in near but not in far space when using a light pen to perform the task. Critically, when using a stick, performance in far space deteriorated, suggesting that extension of reach extended the body, remapping far space as near space. So there is a growing concensus that processing space involves a qualitative distinction between peripersonal and extrapersonal space.

## B) Consistency with studies using the same memory game method that have directly manipulated reachability

Work on the processing of space led directly to examination of reachability and demonstrative use in two studies employing the 'memory game method'. Directly inspired by visual neglect work showing an extension of near space using a tool (S38), Coventry et al. (S34) manipulated reachability in experiments with English and Spanish speakers (two of the languages in the present sample). Participants pointed at objects placed at different distances in front of them either using their hand or a stick. In both languages there was an extension of the use of the proximal term (this, este) when pointing with the stick to the region beyond the end of the hand to the end of the stick. Therefore extending reach led to a corresponding extension in the use of the proximal term.

In another study (S36), participants pointed at objects at locations varying on both the sagittal and lateral planes using their left or right arms. At critical locations where an object to the left or right of the participant was reachable with only one hand, the hand used to point affected choice of this or that to describe object location as a function of whether the pointing hand could indeed reach the object or not.

Taken together, these studies show reachability and not mere distance affects demonstrative choice in two of the 26 languages tested - English and Spanish. Given that the data are very similar in these studies compared to the data found in the present study (see below), this bolsters the view that reachability maps onto demonstrative choice.

## C) Correlations between linguistic and non-linguistic behaviour in previous studies

In another study Coventry et al. (S35) tested participants on a non-linguistic object-location memory task and on the language memory game task using the same object distances and found that performance was correlated between tasks. They argued that, if the use of demonstratives is dependent on processing of space (where a peripersonal/exrapersonal distinction is evident), then
one should find that performance on linguistic and non-linguistic variants of the memory game paradigm should be correlated. This was indeed the case.

## D) Similarity between the present data across languages and data from previous studies on non-linguistic tasks

Supplementary Figure 2 shows percentage change in proximal term use in the present data (collapsed across languages) plotted beside normalised non-linguistic memory error data by distance (from S35). As can be seen in the Figure, the pattern of change in proximal term use across languages mirrors the pattern of change in non-linguistic object-location memory data for the same distances, implicating a relationship between processing of space and demonstrative use in the present data.

In summary, while one cannot definitely rule out a different/more general non-linear distance function, the mapping between reachability and demonstrative choice and the similarity of findings in the present study to non-linguistic spatial data implicates reachability as the most plausible and parsimonious explanation of the distance effect findings observed across languages.

### 4.1.2 Intersubject variability

Supplementary Table 4 shows significant inter-participant variability results for all individual languages.

### 4.2 Main Individual Language Analyses

Arabic (Tunisian)* ${ }^{* 1}$
As can be seen in Supplementary Table 2 (see also Supplementary Tables 61 and 62), separation occurred in the a priori model of Arabic due to the 'no event' condition: the distance effect was so strong that the proximal demonstrative was used in all but 6 trials in Region 1, and never in Region 3 when addressee was seated opposite the speaker. To run a more appropriate analysis of addressee position and distance across Regions 2 and 3, we ran a follow-up model excluding Region 1 (see Supplementary Tables 5 and 6). For completeness the a priori model is presented in section 4.3.

First, the strong correlation between the proximal demonstrative and Region 1 can be seen in the classification table, which never predicts the use of a proximal demonstrative after the elimination of Region 1. The follow-up model in Arabic still revealed a main effect of Region, $F(2,808)=5.237, p=$ $.005, \eta p 2=.013$. The coefficient table shows that the distal and the $3^{\text {rd }}$ term are respectively 25.5 and 38 times more likely to be used in Region 3 compared to the proximal demonstrative.

## Basque*

As can be seen in Supplementary Table 2 (see also Supplementary Tables 63 and 64), separation occurred in the a priori model of Basque due to the 'no event' condition: the distance effect showed a strong correlation between the proximal demonstrative and Region 1, such that the proximal demonstrative was never used in Region 3 while side-by-side. To run a more appropriate analysis of addressee position and distance across Region 2 and 3, we ran a follow-up model excluding Region 1 (see Supplementary Tables 7 and 8 ). The a priori model is presented in section 4.3.

The strong correlation between the proximal demonstrative and Region 1 is supported by the fact that the proximal demonstrative is never predicted after the elimination of Region 1 (see the classification table). The follow-up model in Basque revealed a main effect of Region, $F(2,808)=39.52, p<.001$, $\eta p 2=.089$. The classification table shows that that the proximal demonstrative is not expected to be used at all when Region 1 is taken out of the analysis.

Bulgarian*
As can be seen in Supplementary Table 2 (see also Supplementary Tables 65 and 66), separation occurred in the a priori model of Bulgarian due to the 'no event' condition: the distance effect was so strong that the distal demonstrative was never used in Region 1 while opposite (and only in 2 trials in Region 1 overall). To run a more appropriate analysis of addressee position and distance across Region 2 and 3, we ran a follow-up model excluding Region 1 (see Supplementary Tables 9 and 10). The a priori model is presented in section 4.3.

[^0]The follow-up model showed both main effects: Addressee position, $F(1,500)=6.81, p=.009, \eta p 2=$ .013 , and Region, $F(1,500)=31.608, p<.001, \eta p 2=.059$, but not the interaction. The Region effect showed that, even without Region 1, there was a significant decrease in the use of the proximal demonstrative between Regions 2 and Region 3, with the $\operatorname{Exp}$ (Coefficient) showing the use of distal was 221 times more likely in Region 3 than in Region 2. The main, but weak, effect of addressee position did not come out in the coefficients.

## Cantonese

The Cantonese data displayed a main effect of Region, $F(2,1290)=32.366, p<.001, \eta p 2=.048$ (see Supplementary Tables 11 and 12). The data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2).

## Castilian*

As can be seen in Supplementary Table 2 (see also Supplementary Tables 67 and 68), separation occurred in the a priori model of Castilian due to the 'no event' condition: the distance effect was so strong that the proximal demonstrative was never used in Region 3, and the distal demonstrative was never used in Region 1. To run a more appropriate analysis, we ran a follow-up model excluding Region 1 and the proximal demonstrative (see Supplementary Tables 13 and 14). The a priori model is presented in section 4.3.

The follow-up analysis for Castilian showed a Region effect, $F(1,708)=74.623, p<.001, \eta p 2=.095$, with a clear crossover between the $3^{\text {rd }}$ term and the distal term between Region 2 and Region 3, such that the $3^{\text {rd }}$ term is a clear medial term.

Catalan*
As can be seen in Supplementary Table 3 (see also Supplementary Tables 69 and 70 ), separation occurred in the a priori model of Catalan, due to the 'no event' condition: the distance effect was so strong that the distal demonstrative was never used in Region 1. To run a more appropriate analysis, we ran a follow-up model excluding Region 1 (see Supplementary Tables 15 and 16). The a priori model is presented in section 4.3.

The follow-up analysis for Catalan showed a Region effect, $F(2,856)=20.633, p<.001, \eta p 2=.046$, driven by the distal demonstrative being used far more requently in Region 3 compared to Region 2.

## Danish

The Danish data showed a main effect of Region, $F(2,1218)=43.522, p<.001, \eta p 2=.067$ (see Supplementary Tables 17 and 18). The data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2).

## Dutch

The Dutch data showed a main effect of Region, $F(2,1146)=29.328, p<.001, \eta p 2=.049$ (see Supplementary Tables 19 and 20). The data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2).

## English

The English data showed a main effect of Region, $F(2,1146)=29.238, p<.001, \eta p 2=.049$ (see Supplementary Tables 21 and 22). The data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2).

## Estonian

The Estonian data showed a main effect of Region, $F(2,1506)=25.883, p<.001, \eta p 2=.033$ (see Supplementary Tables 23 and 24). The data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2).

## Finnish

The Finnish data showed a main effect of Region, $F(4,950)=16.872, p<.001, \eta p 2=.066$, and an interaction between region and addressee position, $F(4,950)=4.724, p=.001, \eta p 2=.02$ (see Supplementary Tables 25 and 26). The data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger negative coefficient for Region 3 compared to Region 2). The interaction is driven by a decrease in odds of distal term use in Region 3 when interlocutors are face-to-face, in which the $3^{\text {rd }}$ term is used more often.

## Georgian*

As can be seen in Supplementary Table 2 (see also Supplementary Tables 71 and 72), separation occurred in the a priori model of Georgian due to the 'no event' condition: the distance effect was so strong that the proximal demonstrative was used in all but 2 trials in Region 1. To run a more appropriate analysis of addressee position and distance across Region 2 and 3, we ran a follow-up model excluding Region 1 (see Supplementary Tables 27 and 28). The a priori model is presented in section 4.3.

The follow-up Georgian model showed main effects of Addressee position, $F(2,400)=18.339, p<$ $.001, \eta p 2=.084$, Region, $F(2,400)=14.714, p<.001, \eta p 2=.069$, and the interaction, $F(2,400)=$ $4.019, p=.019, \eta p 2=.02$. The coefficients show that the distal demonstrative is 45 times more likely to be used in Region 3, when the addressee is seated opposite and all else remains the same.
Looking at the frequency table it can be seen that the distal demonstrative is only used in 5 trials when seated side-by-side and behaves like a person-centred term.

## German*

As can be seen in Supplementary Table 3 (see also Supplementary Tables 73 and 74), separation occurred in the a priori model of German due to the 'no event' condition: the distance effect was so strong that the proximal demonstrative was used in only 3 trials in Region 3. To run a more appropriate analysis, we ran a follow-up model excluding the proximal demonstrative (see Supplementary Tables 29 and 30). The a priori model is presented in section 4.3.

The German follow-up analysis showed a main effect of Region, $F(2,754)=11.764, p<.001, \eta p 2=$ .03. This analysis shows that there is a small effect of distance on the distal and the $3^{\text {rd }}$ term demonstratives in Region 3.

## Italian

The Italian data showed a main effect of Region, $F(2,1074)=73.768, p<.001, \eta p 2=.121$, and an Addressee position*Region interaction, $F(2,1074)=3.613, p=.027, \eta p 2=.007$ (see Supplementary Tables 31 and 32). The frequency data show significantly decreasing proximal demonstrative use beyond Region 1. The coefficient table shows that the use of the proximal demonstrative was higher in Region 2 when the experimenter was seated opposite.

## Japanese

The Japanese data showed main effects of Region, $F(4,1212)=24.077, p<.001, \eta p 2=.074$, Addressee position, $F(2,1212)=6.165, p=.002, \eta p 2=.01$, and an interaction between distance and addressee position, $F(4,1212)=3.027, p=.017, \eta p 2=.01$ (see Supplementary Tables 33and 34). The interactions do not come out in the coefficients, but may be due to the fact that the proximal demonstrative (kono, the baseline in these comparisons) is impervious to addressee position changes, whereas the distal (ano) and $3^{\text {rd }}$ term (sono) are affected by addressee position in Region 2 and 3 , showing that the use of the $3^{\text {rd }}$ term increases from $25.49 \%$ to $36.43 \%$ when the addressee is seated opposite. The data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger negative coefficient for Region 3 compared to Region 2 when comparing to the distal term (ano) (other way round for the $3^{\text {rd }}$ term (sono)). The addressee position effect shows an increase of the odds of the use of the $3^{\text {rd }}$ term compared to the distal term, when interlocutors are seated face-toface.

## Korean*

As can be seen in Supplementary Table 3 (see also Supplementary Tables 75 and 76), separation occurred in the a priori model of Korean due to the 'no event' condition: the distance effect was so strong that the $3^{\text {rd }}$ term demonstrative was never used in Region 1 while speaker and addressee were side-by-side. To run a more appropriate analysis, we ran a follow-up model excluding Region 1 (see Supplementary Tables 35 and 36 ). The a priori model is presented in section 4.3.

As the distance effect is driven by the difference between Region 1 vs Region 2 and Region 3, taking out Region 1 means the distance effect doesn't come out in the a posteriori model (however, the distance effect can be clearly seen in Supplementary Table 2; the proximal demonstrative is used in $93.7 \%$ of Region 1 trials, and $91.8 \%$ of proximal uses was in Region 1). The Korean follow-up analysis showed a main effect of addressee position, $F(2,784)=19.729, p<.001, \eta p 2=.048$, in which the $3^{\text {rd }}$ term is used 4.5 times more when the addressee is seated opposite compared to side-by-side.

## Latvian

The Latvian data (see Supplementary Tables 37 and 38) showed a main effect of Region, $F(2,1146)$ $=20.087, p<.001, \eta p 2=.034$. The data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2).

## Lithuanian

The Lithuanian data (see Supplementary Tables 39 and 40 ) showed a main effect of Region, $F(4$, $1140)=24.182, p<.001, \eta p 2=.078$, and an interaction between distance and addressee position, $F(4,1140)=2.821, p=.024, \eta p 2=.01$. The interaction is driven by the distal term, which is used more often when the addressee is seated opposite the speaker. Furthermore, the data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2). The addressee position effect shows differences in odds of proximal versus distal use, showing proximal demonstratives are used more frequently in Region 1 when interlocutors are seated opposite compared to side-by-side, while the distal demonstrative is used more in Region 3 when seated opposite.

## Maltese

The Maltese data (see Supplementary Tables 41 and 42) showed a main effect of Region, $F(2,1218)$ $=82.384, p<.001, \eta p 2=.119$. The data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2).

## Mandarin

The Mandarin data (see Supplementary Tables 43 and 44) showed a main effect of Region, $F(2$, $1218)=113.005, p<.001, \eta p 2=.157$, and an interaction between region and addressee position, $F(2,1218)=4.057, p=.018, \eta p 2=.007$. The interaction shows higher odds ( 1.6 times more likely) for proximal demonstrative use in Region 2 when seated face-to-face ( $p=.004$ ). The frequency table shows decreasing proximal demonstrative use beyond Region 1.

## Marathi

The Marathi data (see Supplementary Tables 45 and 46) showed a main effect of Region, $F(2,714)=$ $12.156, p<.001, \eta p 2=.033$. The data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2).

## Nepali

The Nepali data (see Supplementary Tables 47 and 48) showed a main effect of Region, $F(2,1146)=$ $153.823, p<.001, \eta p 2=.212$. The data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2).

## Norwegian

The Norwegian data (see Supplementary Tables 49 and 50 ) showed a main effect of Region, $F(2$, $822)=40.08, p<.001, \eta p 2=.089$. The data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2).

## Telugu

As can be seen in Supplementary Table 2 (see also Supplementary Tables 77 and 78), separation occurred in the a priori model of Telugu due to the 'no event' conditions: the distance effect was so strong that proximal demonstratives were never used in Region 3, while distal demonstratives were never used in Region 1. This means that a full model cannot be run for Telugu: the data shows almost no variance based on addressee position, while the distance effect is a very strong predictor of demonstrative use. The a priori model is presented in section 4.3.

## Tseltal

The Tseltal data (see Supplementary Tables 51 and 52) showed a main effect of Region, $F(2,641)=$ $21.495, p<.001, \eta p 2=.063$. The data show significantly decreasing odds of proximal demonstrative use beyond Region 1.

## Turkish

The Turkish data (see Supplementary Tables 53 and 54 ) showed a main effect of Region, $F(4,1212)$ $=29.14, p<.001, \eta p 2=.088$. The data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2).

## Vietnamese

Note that 2 of the 5 original Vietnamese demonstrative options were used $<2 \%$ of the time, and were eliminated as described in the analysis plan. The Vietnamese data (see Supplementary Tables 55 and 56) showed a main effect of Region, $F(4,1081)=24.24, p<.001, \eta p 2=.082$, with decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2).

Võro
The Võro data (see Supplementary Tables 57 and 58) showed a main effect of Region, $F(4,960)=$ 22.961, $p<.001, \eta p 2=.087$. The data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds of proximal versus distal the further away the object is (stronger coefficient for Region 3 compared to Region 2).

## Yucatec*

As can be seen in Supplementary Table 2 (see also Supplementary Tables 79 and 80 ), separation occurred in the a priori model of Yucatec due to the 'no event' condition: the distance effect was so strong that the proximal demonstrative was never used in Region 3. To run a more appropriate analysis of addressee position and distance across Regions 1 and 2, we ran a follow-up model excluding Region 3 (see Supplementary Tables 59 and 60). The a priori model is presented in section 4.3.

The follow-up model in Yucatec showed a main effect of Region, $F(1,497)=34.875, p<.001, \eta p 2=$ .066. The coefficients show that the distal demonstrative is 11.48 times more likely to be used in Region 2 compared to the proximal demonstrative.
4.3 A priori models in which separation occurred due to 'no-events': zero values.

For completeness, we present the a priori planned analyses in this section. These are models run on data including zero-values, which causes separation in the models. This means that the model estimates unrealistic coefficients, and effect sizes will be greatly exaggerated.

Arabic (Tunisian) (*Interpret with caution, separation occurred in the model due to zero values)

The Arabic data showed main effects of Addressee position, $F(2,1212)=40.216, p<.001, \eta p 2=$ .062 and Region, $F(4,1212)=85.772, p<.001, \eta p 2=.221$, and a Region x Addressee interaction, $F(4,1212)=26.911, p<.001, \eta p 2=.082$. The interaction shows significant interaction effects of addressee position on the $3^{\text {rd }}$ term, at both Region 2 and 3 ( $p<.001$ ), although it is important to note the ' 0 -value' in the frequency table at the Region 1 by Opposite combination. Furthermore, the data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger negative coefficient for Region 3 compared to Region 2).

## Basque (*Interpret with caution, separation occurred in the model due to zero values)

The Basque data showed main effects of Addressee position, $F(2,1212)=40.727, p<.001, \eta p 2=$ .063 , Region, $F(4,1212)=163.384, p<.001, \eta p 2=.35$, and the interaction, $F(4,1212)=39.638, p<$ $.001, \eta p 2=.116$. The coefficients show that the interaction is driven by the use of the $3^{\text {rd }}$ term in both Regions 2 and 3 compared to Region 1 ( $p<.001$ ), in which the $3^{\text {rd }}$ term is used less frequently when the addressee is seated opposite, although it should be noted that there is a 0 -value in the Region 1, $3^{\text {rd }}$ term, side-by-side cell in the frequency table. The addressee position effect is driven by the $3^{\text {rd }}$ term as well, which is used significantly less frequently when the addressee is seated opposite the speaker. Furthermore, the data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2).

Bulgarian (*Interpret with caution, separation occurred in the model due to zero values)
The Bulgarian data showed both main effects: Addressee position, $F(1,750)=246.54, p<.001, \eta p 2$ $=.247$, Region, $F(2,750)=99.997, p<.001, \eta p 2=.211$, and the Position*Region interaction, $F(2$, $750)=136.562, p<.001, \eta p 2=.267$. It is however important to note the 0 -value at the Opposite by Region 1 combination in the frequency table, as each model would struggle with rare events/empty values. The frequency table shows decreasing proximal demonstrative use beyond Region 1.

## Castilian (*Interpret with caution, separation occurred in the model due to zero values)

The Castilian data showed a main effect of Region, $F(3,1068)=8685.471, p<.001, \eta p 2=.961$, and an interaction effect, $F(2,1068)=55.629, p<.001, \eta p 2=.094$. The frequency table shows that there is a clear distinction between proximal and distal terms, such that the proximal demonstrative is almost always used in Region 1, but never in Region 3; while the distal is never used in Region 1. Furthermore, the data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2). The interaction is not supported by the coefficients calculation, where all $p$ values are 1.

Catalan (*Interpret with caution, separation occurred in the model due to zero values)
As can be seen in Table 3, separation occurred in the a priori model of Catalan, due to the 'no event' condition: the distance effect was so strong that the distal demonstrative was never used in Region 1. Furthermore, there is an almost complete lack of variance based on addressee position in Regions 1 and 3.

The Catalan model showed a main effect of region, $F(4,1284)=7373.315, p<.001, \eta p 2=.958$ and an interaction, $F(4,1284)=6.343, p<.001, \eta p 2=.019$. This is due to separation within the multinomial model arising from the 'no event' condition and the subsequent implausible parameter estimates (N.B. the distal demonstrative was never used in Region 1).

Georgian (*Interpret with caution, separation occurred in the model due to zero values)
The Georgian data showed main effects of Addressee position, $F(2,61)=56.442, p<.001$, $\eta p 2=$ .649 , Region, $F(4,600)=176.929, p<.001, \eta p 2=.541$, and the interaction, $F(4,600)=105.343, p<$ $.001, \eta p 2=.413$. The coefficients show the interaction is apparent at almost every level, in both Distal term, opposite by Region 2 and 3 ( $p<.001$ ), and with the $3^{\text {rd }}$ term, opposite by Region $2(p=.011)$. The addressee position effect is driven by a decrease in the use of the $3^{\text {rd }}$ term (from $43.46 \%$ when seated side-by-side to $20.26 \%$ when seated opposite). Lastly, the data show significantly decreasing
odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2). Note that this effect does not come out as strongly in the coefficients of the distal term, but as can be seen in the frequency table, the use of the distal demonstrative is a rare event when seated side-byside.

German (*Interpret with caution, separation occurred in the model due to zero values)
The German data showed main effects of Addressee position, $F(2,1140)=120.804, p<.001, \eta p 2=$ .153 , Region, $F(4,1140)=299.437, p<.001, \eta p 2=.512$, and the interaction, $F(4,1140)=109.961, p$ $<.001, \eta p 2=.278$. As can be seen in the coefficients table, the interaction is driven by the opposite by Region 3 cell of the design, contrasting with a proximal demonstrative 0 -value. The addressee position effect does not come out in the coefficients, but in the frequency table it can be seen that the proximal demonstrative is used more often when the addressee is seated opposite the speaker, mostly taking from the distal demonstrative. Furthermore, the data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2).

Korean (*Interpret with caution, separation occurred in the model due to zero values)
The Korean data showed main effects of Region, $F(4,1176)=120.864, p<.001, \eta p 2=.171$, Addressee position, $F(2,1176)=74.241, p<.001, \eta p 2=.202$, and the interaction, $F(4,1176)=$ 66.993, $p<.001, \eta p 2=.186$. The data show significantly decreasing odds of proximal demonstrative use beyond Region 1. The addressee position effect represents the increased use of the $3^{\text {rd }}$ term when the addressee is seated opposite the speaker, while the interaction shows that this increase happens specifically in Regions 2 and 3, when the addressee is seated opposite. As in Japanese, the addressee position effect occurs between the distal and $3^{\text {rd }}$ term.

Telugu (*Interpret with caution, separation occurred in the model due to zero values)
The Telugu frequency data show such a strong effect of distance, and an almost complete lack of variance based on addressee position, that while the model runs it cannot do so reliably (as evidenced by the high confidence intervals). There a main effect of Region, $F(1,5)=57012.579, p<$ $.001, \eta p 2=1$. The data show significantly decreasing odds of proximal demonstrative use beyond Region 1, while the coefficients show a stronger decline of the odds the further away the object is (stronger coefficient for Region 3 compared to Region 2).

Yucatec (*Interpret with caution, separation occurred in the model due to zero values)
The Yucatec data showed a main effect of Region, $F(2,20)=158519.433, p<.001, \eta p 2=1$. Note that the combination of proximal and distal demonstratives was only used in 3 trials, so was not included in the analysis. Furthermore, the distal demonstrative is the clear default for referential use in the experimental setting with a total of $85 \%$ of produced demonstratives being distal. Apart from this, the pattern of data in Yucatec mirrors other languages, with proximal used mostly in Region 1, with significantly less proximal use the further the object is placed (stronger coefficient for Region 3 compared to Region 2).
4.2 Supplementary Figures

Supplementary Figure 1. A schematic representation of the experimental setup. The Speaker (participant) is seated at a table, with the Addressee either sitting side-by-side, or opposite the speaker. Color-coded locations mark distance increases of 25 cm each. In the schematic, three conceptual regions are represented, such that Region 1 and Region 2, are just as far from the speaker as respectively Region 3 and Region 2 are from the Addressee, when seated opposite.

Supplementary Figure 2. Normalized proximal term use (collapsed across the 29 languages; red bars) plotted beside normalized (non-linguistic) object-location memory data from (32) (with/without explicit verbal interference; green/blue bars; see 32).

## 5. Supplementary Tables

Supplementary Table 1. Participant demographic information per language.

|  | N (excluded) | Female | Male | Age (M, SD) |
| :---: | :---: | :---: | :---: | :---: |
